Preface

The research investigation described herein was conducted as part of the Coastal Inlets Research Program (CIRP) under Work Unit 32935, “Inlet Laboratory Investigations.” Overall program management for CIRP is directed by Headquarters, U.S. Army Corps of Engineers (HQUSACE). Program Monitors for the CIRP at HQUSACE are Messrs. Barry W. Holliday and Charles B. Chesnutt. The Program Manager was Mr. Clark McNair followed by Dr. Nicholas C. Kraus, U.S. Army Engineer Research and Development Center (ERDC), Coastal and Hydraulics Laboratory (CHL), Vicksburg, MS. Mr. William C. Seabergh is Principal Investigator of the Inlet Laboratory Investigations Work Unit.

The mission of the CIRP is to conduct applied research to improve USACE capability to manage federally maintained inlets, which exist on all coasts of the United States (including Atlantic, Gulf, Pacific, and the Great Lakes regions). Objectives are to (a) make management of channels--design, maintenance, and operation--more effective to reduce the cost of dredging, and (b) preserve the adjacent beaches in a systems approach that treats the inlet and beach together. To achieve these objectives, CIRP includes work units on short-wave and circulation modeling, channels and adjacent shorelines, inlet scour, laboratory investigations, field investigations, and technology transfer.

This study was conducted by CHL personnel under the general direction of Dr. James R. Houston, former Director of CHL, and Mr. Thomas W. Richardson, current Director. The experiment series was conceived and initially designed by Dr. Kraus. Direct guidance was provided by Mr. Dennis Markle, Chief, Harbors and Entrances Branch, CHL. Experiments were conducted by Mr. John Evans, Civil Engineering Technician, and Ms. Leonette J. Thomas, Mathematician, under the direction of Mr. Seabergh, all of the Harbors and Entrances Branch. Mr. John Mahoney of the ERDC Information Technology Laboratory provided instrumentation support. This report was prepared by Mr. Seabergh, Mr. William R. Curtis, Coastal Evaluation and Design Branch, CHL, Ms. Thomas, and Mr. Kent K. Hathaway, Field Research Facility, Coastal Engineering Branch, CHL. Word Processing and formatting were completed by Ms. J. Holley Messing, Coastal Engineering Branch. Dr. Zeki Demirbilek, Harbors and Entrances Branch; Dr. Lihwa Lin, Coastal Engineering Branch; and Mr. Gene Berek of Metocean, Coastal and Offshore Technologies, provided suggestions from a user’s point of view. Technical consultation for Coastal Inlets Imaging System (CIIS) development was provided by Dr. Robert Holman and Mr. John Stanley, Oregon State University, Corvallis, and Dr. K. Todd Holland, U.S. Naval Research Laboratory. Dr. Holland also provided

computational code development consultation for the estimation of video-derived wave number moments and the extension to estimates of wave direction.

At the time of publication of this report, Dr. James R. Houston was Director of ERDC and COL John W. Morris, III, EN, was Commander and Executive Director.

1 Introduction

Waves at tidal inlets refract, diffract, and shoal as they travel from deeper water, over the ebb shoal, and into the navigation channel toward the bay. How waves transform as they change direction and height is of interest to navigation because the knowledge will assist in understanding sediment transport in the inlet, especially near the navigation channel, and anticipating wave-related processes inside the inlet, such as shoreline erosion and accretion. In particular, waves diffract where they encounter a jetty, breakwater, or other discontinuity. Diffraction at a jetty can cast a wave shadow either inside the inlet or on the adjacent beach, depending on the incident wave direction. Controlled measurements of wave diffraction on a sloping beach are lacking, yet this combined transformation process is ubiquitous at all coastal inlets.

Background

The purpose of these laboratory experiments was to measure wave height and direction in typical coastal inlet conditions with emphasis on wave diffraction and refraction. At many locations, coastal structures are built to reduce wave height and minimize sedimentation of the navigation channel. In this study, a shore-parallel breakwater and a dogleg jetty were examined in the seaward side of the inlet. Measurements were also made on the bay side of the inlet for a jettied and nonjettied condition.

Figure 1 illustrates diffraction and refraction on the bay side of Shinnecock Inlet, Long Island, New York. Coastal inlet entrance channels are typically incised in relatively shallow depths and are thus susceptible to movement of sediment into the channel by coastal currents of tidal and wind wave-generated origin. The entrance channel may be flanked by jetties and/or breakwaters to reduce sediment influx to the channel and to provide protection for navigation. In order to understand the mechanisms of sediment movement into the channel, the simulation of the wind-wave field is a central component of any modeling study of techniques to minimize channel shoaling. Historically, for coastal problems at sites with complex bathymetry and protective structures such as jetties, breakwaters, and groins, studies were conducted in physical models.

Figure 1. Wave diffraction and refraction into Shinnecock Bay, Long Island, New York

With the advancement of numerical techniques to simulate wind-waves, laboratory data sets have proven beneficial for checking the reliability of the numerical code. As part of the Coastal Inlets Research Program (CIRP),¹ this study was performed to provide data to support numerical model development and to understand wave refraction-diffraction in the vicinity of coastal inlet entrance channels. In particular, wave height and wave direction were measured throughout the inlet region.

Previous laboratory simulations of refraction-diffraction phenomena have been conducted on flat or uniformly sloping bottom contours in the vicinity of a jetty, offshore breakwater, or two semi-infinite offshore breakwaters with a gap. Harms (1979) examined diffraction behind a shore-connected breakwater. Hales (1980) examined wave refraction-diffraction behind a shore-connected breakwater with a uniform beach slope. Briggs, Thompson, and Vincent (1995) studied diffraction behind a semi-infinite breakwater on a flat bottom. Yu et al.

¹ For convenience, symbols and abbreviations are listed in the notation (Appendix A).

(2000) performed experiments of refraction-diffraction on a flat bottom, a sloping bottom, and a third configuration with a flat bottom with a channel incised through two semi-infinite breakwaters. Such studies have measured or examined wave height, but not wave direction. The present study was designed to measure both wave height and direction.

Refraction and Diffraction Processes

Some of the following material is taken from Hales (1980), who presents background material describing the refraction and diffraction of water waves. Except in deep water, the wave phase speed depends on water depth. Because wave celerity decreases as depth decreases, the wavelength must also decrease for the period to remain constant. Phase velocity varies along the crest of a wave propagating at an angle to underwater contours because that part of the wave in deeper water moves faster than that part in shallower water. This variation causes the wave crest to bend toward alignment with the contours. The bending of wave crests in response to changes in bottom topography, called refraction, depends on the relation of water depth to wavelength and is analogous to refraction of other types of waves such as light, where, in the case of water waves, water depth determines the refractive index. A basic assumption in wave refraction theory is the conservation of energy between orthogonals (i.e., no diffraction of energy along wave crests).

Diffraction of water waves is the phenomenon where wave energy propagates into the sheltered lee of structures apart from bathymetric refraction. Here, wave crests bend (even in constant water depth) and gradients of wave height exist along the wave crest. The theory of water wave diffraction can be explained by Huygen's principle. Each point of an advancing wave crest may be considered as the center of a secondary circular wave that advances in all directions. The resultant shape of the crest is the sum of all these secondary waves. In a straight-crested wave, the envelope of the secondary waves is a straight line also. As the wave passes an obstruction, the energy at a certain point is a vector combination of all the circular waves emitted by every point of the passing wave train.

The bathymetry in the vicinity of coastal structures can be irregular, and the phenomenon of refraction can occur in conjunction with diffraction. The historical procedure to determine the wave-height variation behind the coastal structure was to construct refraction diagrams from the sea toward the structure, then construct diffraction diagrams for three or four wavelengths shoreward of the structure and then refract the last wave crest on toward the shoreline (Hales 1980). Mobarek (1962) experimentally investigated refraction-diffraction and found that this "rule of thumb" was reasonable for medium-period waves, but for longer periods, transformation by refraction over a shoaling bottom should be taken into consideration.

Various numerical approaches for numerical work examining diffraction-refraction include those of Liu and Mei (1976), Liu and Lozano (1979), Houston (1980), and Goda (1985).

Objectives

In this report, combined wave diffraction, refraction, and shoaling were examined through physical-model measurements made in an idealized inlet. One goal of the study was to provide the data to develop and validate numerical models of refraction, diffraction, and shoaling at an inlet that will help to better understand the processes. The other goal was to validate a video system developed for measurement of wave direction to develop improved technology for calculating wave transformation at inlets.

Scope

Following this Introduction are the experiment design (including the laboratory facility, the instrumentation, and the experimental series), described in Chapter 2; wave direction measurement technique and experiment procedures discussed in Chapter 3; and data analysis (including sequence of events, calibration, sampling, data analysis methods, data format, and example plots) presented in Chapter 4. Chapter 4 discusses and presents results of data collection for four structural configurations. Note that Chapter 5 presents a new technique for determining wave direction that was developed in this study. Also presented are comparisons of video and velocity meter measurements of wave angle. Chapter 6 summarizes the report and presents conclusions.

2 Laboratory Facility, Equipment, and Experiment Design

As part of the CIRP, a physical model facility was created to address research and field problems of tidal inlets (Seabergh 1999). The model and appurtenances necessary to study inlet problems are discussed in this chapter.

Idealized Inlet Facility

An idealized inlet was designed to fit in a 46-m- (150-ft-) wide by 99-m- (325-ft-) long concrete basin with 0.6-m- (2-ft-) high walls. The approach was to design an inlet with simplified bathymetry and relatively steep beach slopes so additional features (such as an ebb shoal) could easily be added. Plans included using fine sand as both a tracer and as a fully mobile bed that could be placed over the concrete bottom in a thick veneer. A 1:50 undistorted scale was assumed to determine reasonable inlet dimensions to model; however, other scales can easily be assumed to accommodate studies of specific processes with the simplified bathymetry.

Figure 2 shows the facility and basin area. The Idealized Inlet Facility is connected to a large sump (not shown, volume of 1.98×10^6 L (523,000 gal)) for water exchange. Tides may be produced in the ocean of the facility to drive tidal currents into and out of the inlet bay. A constant inflow is introduced from the sump into the ocean of the facility, while a rolling gate either reduces or increases flow area over an exit pipe into the sump, which causes ocean rise or fall, respectively. The rolling gate is regulated by a controller connected to a feedback loop comparing actual to desired water level. The two cylinders in Figure 2 are storage tanks each holding 182,000 L (48,000 gal) water. The tanks can be activated to simulate a much larger bay area by storing flood tide water and releasing it back to the bay to flow to the ocean during ebb flow. Pumps and control valves associated with this procedure are located adjacent to the storage tanks.

A steady-state flow may also be established for simulating ebbing or flooding currents. The piping system appears in Figures 2 and 3. Water is either collected (flood flow) or distributed (ebb flow) through a system of manifolds in the bay

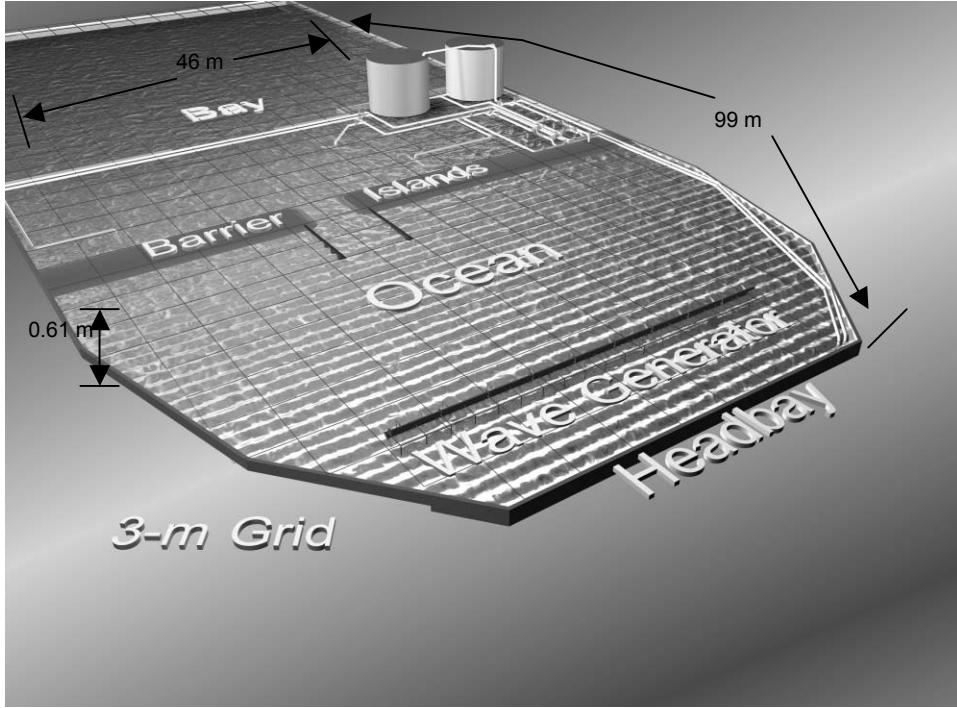

Figure 2. Idealized inlet model research facility

that may be adjusted for one, two, or three bay channels or a uniform flow across the bay. Water is either released (flood flow) or taken from (ebb flow) the ocean headbay to complete the circulation energized by the pumps located in the upper right side of Figure 2.

Figure 3 shows bottom contours at a 1:50 scale. The ocean-side parallel contours were specified by applying an equilibrium profile equation from Dean (1977):

$$d = Ax^{0.67} \quad (1)$$

where

d = still-water depth

x = distance offshore

and A is determined by sediment characteristics. A value of $A = 0.24 \text{ ft}^{1/3}$ was specified to represent a relatively steep beach. The contoured beach slope extends to the 18.3-cm (0.6-ft) mean low water (mlw) depth (or 9.1 m (30 ft) scaled by 1:50).

The inlet throat region converges to a depth of 15.2 cm (or if scaled to 1:50, to a depth of 7.6 m (25 ft)) relative to an mlw datum. The minimum width is 267 cm (8.76 ft) (or if scaled by 1:50, 133.4 m (438 ft)) across the inlet between mlw contours. Figure 4 shows the inlet with a parallel jetty configuration.

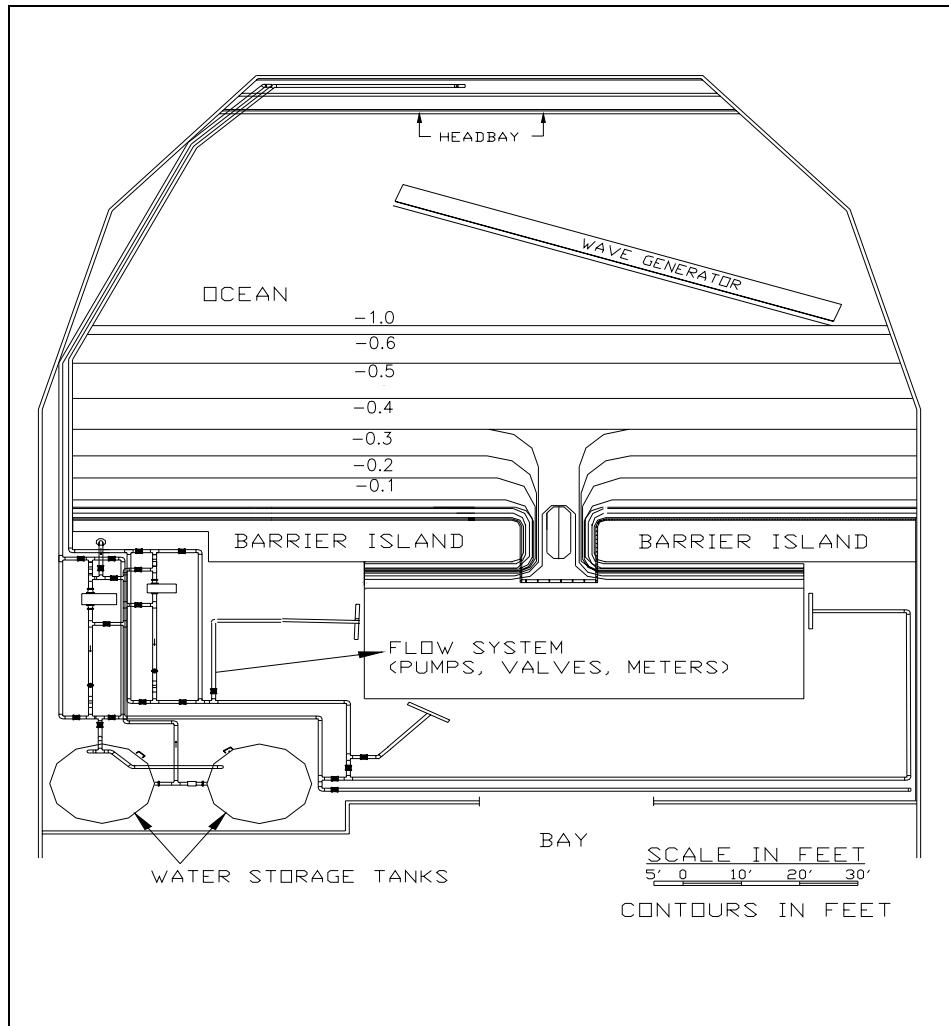

Figure 3. Model facility showing bathymetry (measurements given in feet may be converted to meters by multiplying by 0.3048)

Based on Froude's model law (Hughes 1993) and the linear scale of 1:50, the model-prototype relations in Table 1 were derived. Dimensions are in terms of length ℓ and time t . Figure 4 shows the model inlet during testing. As mentioned previously, other scales may be assumed for the bathymetric contours, so different scaling relationships would apply from these in Table 1.

A movable, 24.4-m- (80-ft-) long, unidirectional wave generator (Figure 2) was located on the ocean side of the facility to produce either irregular or monochromatic waves of fixed direction (long-crested waves). Unscaled wave periods could be varied from 0.5 to about 3 sec and wave heights to 10 cm (0.3 ft) (at the generator location and for this model configuration). Wave angle (incident wave direction) was varied for specific tests by moving the generator on its casters.

Table 1
Model-Prototype Scale Relations at 1:50 Undistorted Scale

Characteristic	Dimension	Model-Prototype Scale Relation
Length	ℓ	$\ell_r = 1:50$
Area	ℓ^2	$A_r = \ell_r^2 = 1:2,500$
Volume	ℓ^3	$V_r = \ell_r^3 = 1:125,000$
Time (tidal and short wave period)	t	$t_r = \sqrt{\ell_r} = 1:7.07$
Velocity	ℓ/t	$U_r = \ell_r/t_r = 1:7.07$

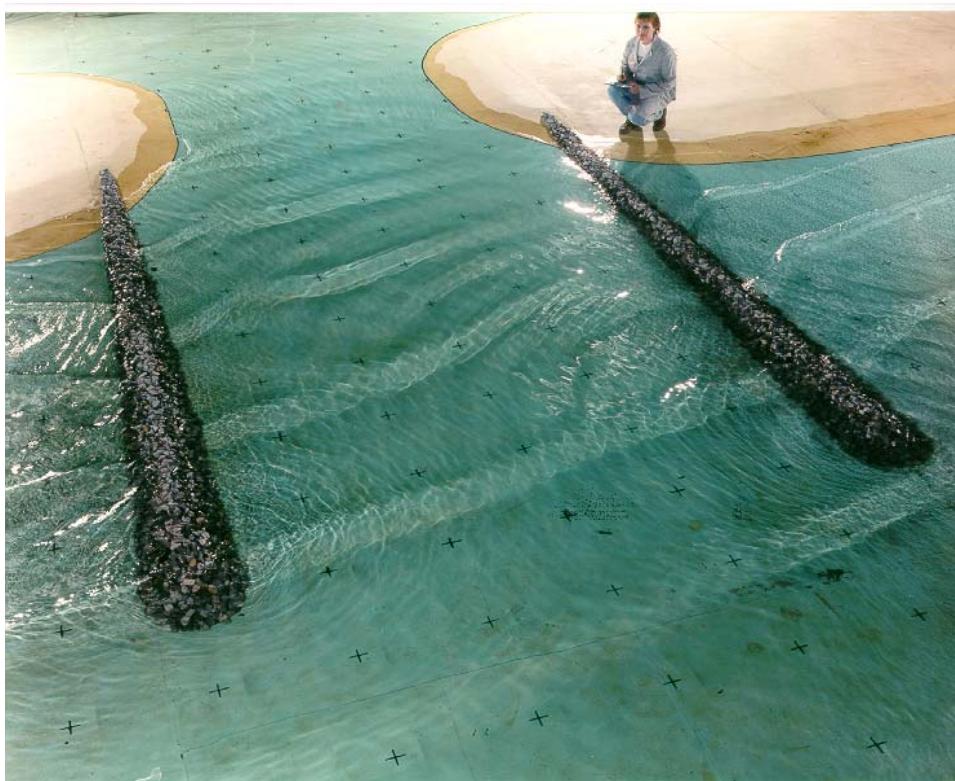

Figure 4. Idealized inlet entrance channel with oblique wave approaching inlet (spacing 62 cm (2.0 ft) between "+" marking on research facility basin floor)

Instrumentation and Calibration

Wave height and period data were collected on electrical capacitance wave gauges, which were calibrated daily with a computer-controlled procedure incorporating a least-square fit of measurements at 11 steps. This averaging technique, using 21 voltage samples per gauge, minimizes the errors of slack in the gear drives and hysteresis in the sensors. Typical calibration errors are less than 1 percent of full scale for the capacitance wave gauges. Wave signal generation and data acquisition were controlled by a DEC MicroVax I computer.

Water velocity data were collected with SonTek 2D Acoustic Doppler Velocimeters (ADV) with a side-looking probe that is oriented to measure x-y horizontal velocity information in a horizontal plane. Samples were collected at 20 Hz, though the instrument makes 250 pings/sec and averages for each output sample. Accuracy is 0.5 percent of the measured velocity, with resolution of 0.1 mm/sec and threshold of 0.1 cm/sec. The probe samples a 0.25-cu-cm volume located 5 cm from the sensor heads. The velocity data were analyzed for wave direction.

The sensor placement locations are discussed in the next section. A gauge rack was designed to hold the wave sensors in a co-linear manner, with a 0.61-m (2.0-ft) separation between gauges. The rack was then moved to other locations for various test runs.

Experiment Design

Four idealized “structural” arrangements, constructed of 3/4-in. marine plywood, were examined. The first was a shore-parallel breakwater (Structure 1), the second was a typical dogleg jetty (Structure 2), and the third and fourth structures were arranged for measurements of diffraction-refraction into the bay for an unjettied (Structure 3) and jettied (Structure 4) inlet. Wave conditions consisted of two irregular waves (0.8 sec, 0.2 ft (6.1 cm) and 1.6 sec, 0.15 ft (4.6 cm)) and one regular wave (0.8 sec, 0.15 ft (4.6 cm)) for all model structure configurations. Shore-normal waves were generated for all structures, and a 20-deg wave from shore normal was created for Structures 1 and 2. The 20-deg wave was created from the same wave-generator location, resulting in increased wave energy for Structure 1 relative to the shore-normal wave and decreased energy for Structure 2 relative to the shore-normal wave.

A flood current was created for the Structure 3 (no jetties) condition. The determination to create a flood current for this condition arose from the observation that currents created by the breaking waves on each beach adjacent to the inlet flowed into the inlet and exited seaward, interacting with the incoming waves. This wave-current interaction caused breaking waves and reduced wave energy entering the bay. Data were collected for both the flood current and no-flood current conditions. For Structure 4, the jetties prevented the longshore currents from entering the channel.

Structure 1, the shore-parallel breakwater (Figures 5 and 6), was placed offshore of the beach in a region with shore-parallel contours. The breakwater extended 9.1 m (30 ft) to the sidewall of the model. The wave generator was initially set parallel to the shoreline, then moved to a 20-deg angle with the shoreline, positioned to enhance increased energy propagation behind the breakwater. Note the partition across the channel that isolated the bay from the ocean. Data collection consisted of wave heights and direction from gauges on movable racks at 20 locations and at 10 fixed locations. Thirty locations were sampled simultaneously for a given instrument arrangement. There were five arrangements of the movable gauge racks for the offshore breakwater, for a total of 100 gauge locations shoreward of the breakwater. Five fixed wave gauges were located on line with the offshore breakwater defining the incident wave that would refract-diffract behind the breakwater. Five additional gauges were placed at the wave generator to define deeper water wave conditions and ensure consistent wave generation. Also placed on the wave gauge rack were two ADVs, which were analyzed to define wave direction. This portion of the data collection was to provide a crosscheck of the wave direction measurements made through analysis of video photography from multiple cameras to determine wave direction.

Structure 2, the dogleg jetty, is shown in Figure 7 with its gauge arrangement depicted in Figure 8. The gauge arrangements of Structures 3 and 4 are shown in Figures 9 and 10, respectively, and photographs of the setups are shown in Figures 11 and 12, respectively. Table 2 summarizes the experiments. Horsehair wave absorber was located on the outside of Structures 1, 2, and 4 to minimize reflection back to the wave generator and ocean basin region. For Structures 1 and 2, the absorber was terminated 0.9 m (3 ft) from the tip of the structure. See Figure 7 for absorber location. For Structure 4, the absorber was placed on the oceanside of each of the parallel jetties, extending to the tip (Figure 12). The absorber extended through the water surface. Chapter 4 contains additional details for each structure.

3 Measurement Procedures and Data Analysis

This chapter provides information on the data collection procedure and analysis. Selected example plots of data are also shown.

Data Sampling and Wave Generation

Following daily calibration of the wave gauges (Chapter 2), and incident wave conditions, the experiments began and both current and wave data were collected. The wave generator was operated for 420 sec with a 10-sec ramp-up and ramp-down time. The wave gauge sampling rate was 20 Hz, so 20,400 water elevation data points were collected at each gauge, and 10,200 additional velocity data samples (initially a 10-Hz sampling rate, but increased to 20 Hz early in the study) for each sensor were collected during a run.

All spectral wave tests were made with a unidirectional JONSWAP wave spectrum using the following spectral parameters:

- a. For the tests with a target wave height H_s of 6.1 cm and peak wave period T_p of 0.8 sec, a wave generator signal was created using the peak enhancement factor γ of 3.3, low and high peak decay frequencies σ_a of 0.07 and σ_b of 0.09, respectively, and Phillips constant α of 0.03198. The low and high cutoff frequencies of the spectrum were set to the frequencies having 3 and 97 percent of the total spectral variance. In these tests, these were 0.998 Hz and 2.839 Hz, respectively.
- b. For the tests with H_s of 4.6 cm and T_p of 1.6 sec, a wave generator signal was created with γ of 3.3, σ_a of 0.07 and σ_b of 0.09, and α of 0.00108. The low and high cut-off frequencies of the spectrum were set to the frequencies having 3 and 97 percent of the total spectral variance. In these tests, these were 0.4989 Hz and 1.4196 Hz, respectively.

Figure 13 shows an example comparison of target and measured spectra at a wave gauge location in front of the wave generator. Figure 14 shows a snapshot of water-surface variation at two gauges.

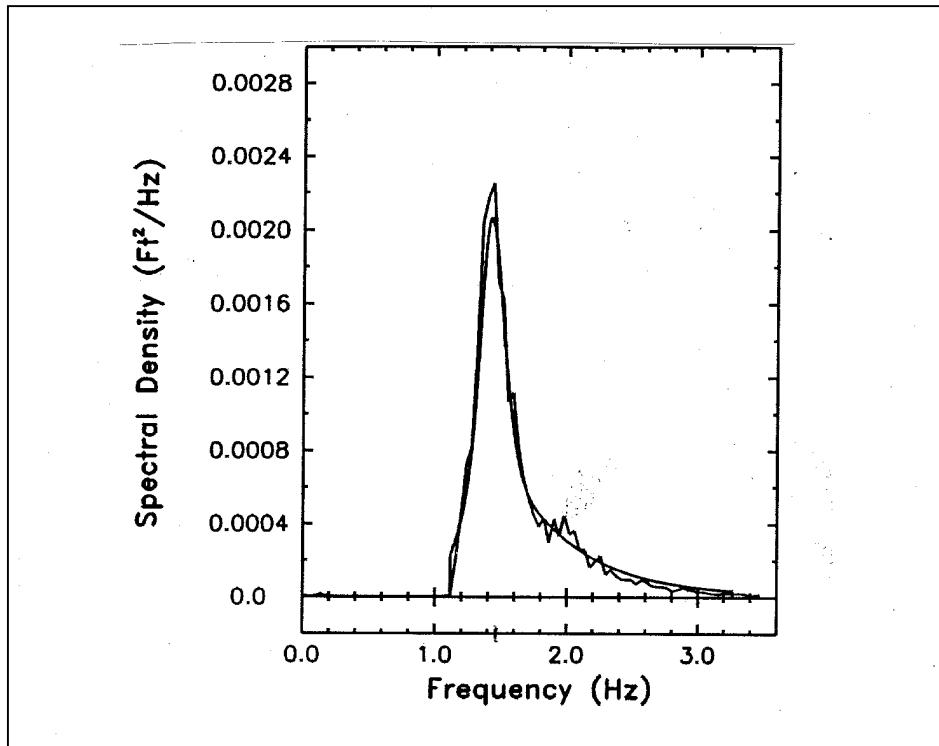

Figure 13. Comparison of targeted and measured spectra for wave generation

Data Analysis

The velocity data were analyzed to determine wave direction with a program adapted from a PUV (pressure and horizontal velocity components) directional wave gauge analysis program as outlined by Earle, McGehee, and Tubman (1995). Because water level variation was unavailable at the location of the current meter probe, the wave direction and energy for each frequency were determined from the harmonics of the directional spectrum related to velocity. These harmonics are calculated from auto- and cross-spectra determined from a Fast Fourier Transform (FFT) of the velocity records.

Wave data were analyzed in two ways. A down-crossing analysis was performed on the time series of water elevations as well as spectral analysis using an FFT. The down-crossing analysis produced the calculated parameters shown in Table 3.

FFT or single-channel frequency domain analysis was performed over the entire 20,400 data points ($\Delta t = 0.05$ sec). In the analysis, the mean was removed and a cosine square taper applied over 10 percent of the data at the beginning and end of the data record. The spectral parameters calculated are listed in Table 4.

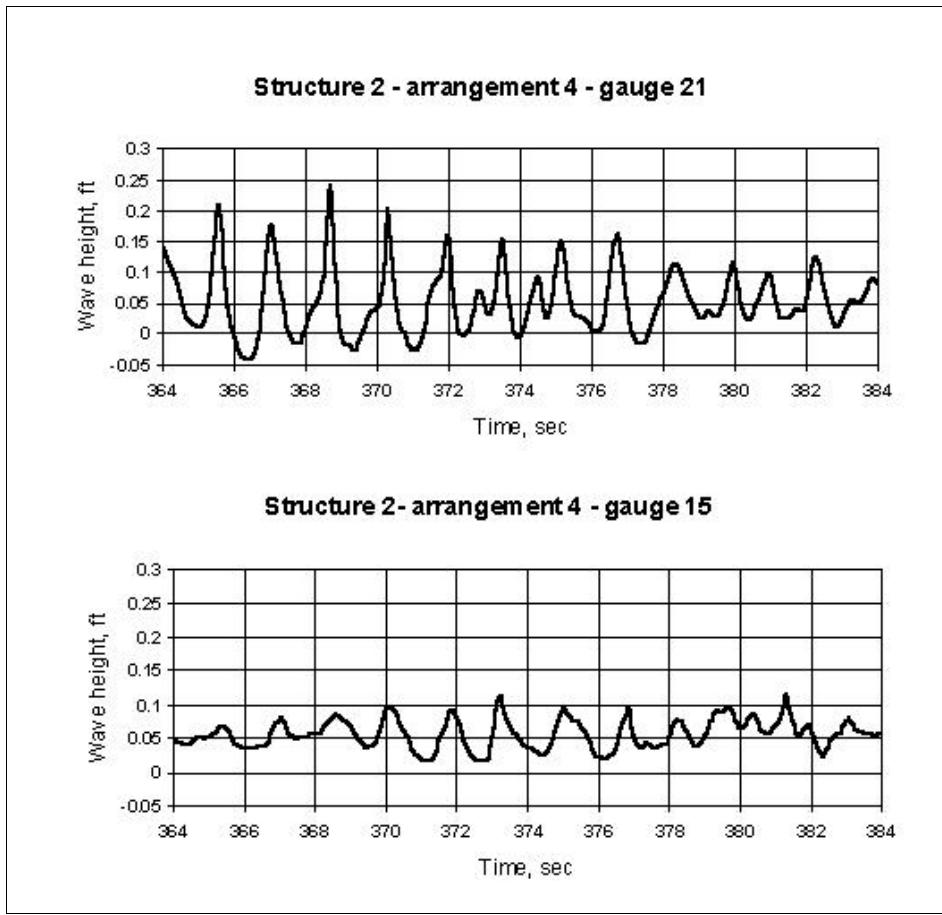

Figure 14. Time series of water-surface elevation η at wave generator (Gauge 21 and Gauge 15)

Tables 3 and 4 list the parameters available from the data analysis, which are available on compact disk (CD) from the Coastal and Hydraulics Laboratory, U.S. Army Engineer Research and Development Center. Water level variation and velocity data are also included in CD format for all experiments discussed in this report.

It should be noted that entire data records were analyzed to produce the tables of wave parameters. It was observed that for Structures 3 and 4 there were some transient and unsteady effects in the wave records, typically at the start of data collection. These effects may have resulted from different processes. First, especially for Structure 3, longshore currents, created by breaking waves along the shoreline, could be observed during these experiments; and these currents were moving into the inlet from both beaches. Once in the inlet, these wave-induced currents would then turn seaward and interact with the incoming waves. Within the narrow inlet, reflected waves from the sides of the inlet appeared to converge and interact at the center of the narrowest and deepest part of the inlet channel. On the bay side of the inlet, slow circulation patterns were created that took a while to develop. The transient effects seemed to be stronger for the

monochromatic waves. Therefore, care should be exercised in analyzing the raw time-series data in either time or frequency domain. It may be appropriate for the user of the data to view the data carefully and select later segments of the data stream for comparison to numerical model estimates.

Table 3
Calculated Wave Parameters from Down-crossing Analysis

Parameter Name	Description
ETABAR	Average water level
ETARMS	Root-mean-squared water level
ETAMAX	Maximum water-surface elevation
ETASD	Standard deviation of water level
RHOHH	Correlation between wave heights
RHOHT	Correlation between heights and periods
HMIN	Smallest wave height
HMAX	Largest wave height
HBAR	Average wave height
H 1/3	Significant wave height, average of highest 33 percent of wave heights
H 1/10	Average of highest 10 percent of wave heights
H 1/20	Average of highest 5 percent of wave heights
H 1/100	Average of highest 1 percent of wave heights
TBAR	Average wave period
T 1/3	Significant wave period, average period of highest 33 percent of waves
T 1/10	Average wave period of highest 10 percent of wave heights
T 1/20	Average wave period of highest 5 percent of wave heights
T 1/100	Average wave period of highest 1 percent of wave heights
WEIBULL ALPHA	For Rayleigh distribution of wave heights, alpha = 2 and beta = 0.5. Truncation of higher wave heights by breaking increases alpha.
WEIBULL BETA	
NO. OF WAVES	Number of waves in record.
H (P=0.5)	Median wave height (exceeded 50 percent)
T (P=0.5)	Median wave period (exceeded 50 percent)

Table 4
Calculated Wave Parameters from Single Channel
Frequency Domain Analysis

Parameter Name	Description
FPC	Peak frequency, CERC method ¹
FPS	Peak frequency, single band
FPD	Peak frequency
TPC	Peak period, CERC method ¹
TPS	Peak period, single band
TPD	Peak period, Delft method
HMO	Wave height, zero moment
QPG	Spectral width parameter (Goda 1970)
EM0	Zeroth moment of the energy spectrum
EM1	First moment of the energy spectrum
EM2	Second moment of the energy spectrum
TO2	Average period, calculated as $(EM0/EM2)^{0.5}$

¹ J. Ahrens. (1983). "Important parameters, irregular waves," Internal Memorandum For Record, 9 December 1983, U.S. Army Engineer Waterways Experiment Station, Coastal Engineering Research Center, Vicksburg, MS.

4 Physical Model Results

The purpose of these laboratory experiments was to measure wave height and wave direction in the lee of coastal structures and inside an inlet entrance to verify numerical techniques and models for combined wave diffraction, refraction, and shoaling. This chapter presents the results of the wave height and direction measurements collected for the four structures. Wave height data were plotted spatially and contoured. Spectral energy density versus frequency plots are also examined. Wave direction measurement techniques and results are discussed in Chapter 5.

Structure 1

The Structure 1 configuration represented a semi-infinite offshore breakwater with a shoreward sloping bottom behind the breakwater (Figure 5) terminating at the beach. Appendix B contains data tables for the gauge arrangement for each experiment. A total of six experimental conditions were studied as noted in Table 2. For an incident wave direction of 0.0 deg, irregular waves of 0.8 sec, 6.1 cm (0.2 ft), and 1.6 sec, 4.6 cm (0.15 ft) and monochromatic waves of 0.8 sec, 4.6 cm (0.15 ft) were produced. The wave generator was repositioned for a 20-deg incident wave direction and the same three wave conditions repeated. Initial experiments with the 0-deg wave approach indicated very small wave heights at the distant wave gauges behind the breakwater, so to obtain additional wave energy penetration behind the breakwater, the 20-deg experiments were performed.

The tables in Appendix B contain gauge number, depth at the gauge, average water surface elevation relative to the still-water level, significant wave period, significant wave height, average wave height, and maximum wave height. The data are arranged in tables for each gauge arrangement, as shown in Figure 5. Appendix C presents contoured dimensional wave height plots. Figure 15 shows the 0.8-sec experiment wave height contours, with mean wave direction given at selected locations as determined from the velocity gauges. The x-y arrows depicted on the plots indicate the basin x-y position that corresponds to the plot origin (0,0). Appendix J contains sample spectral energy density versus frequency plots for selected wave gauge locations. The overall basin bathymetry, the shore-parallel breakwater structure, the dogleg jetty structure, and the parallel jetties structure are referenced in Appendix K. The large volume of data has been placed on the accompanying CD. The location of the wave gauges and breakwater within the coordinate system is given in Appendix L.

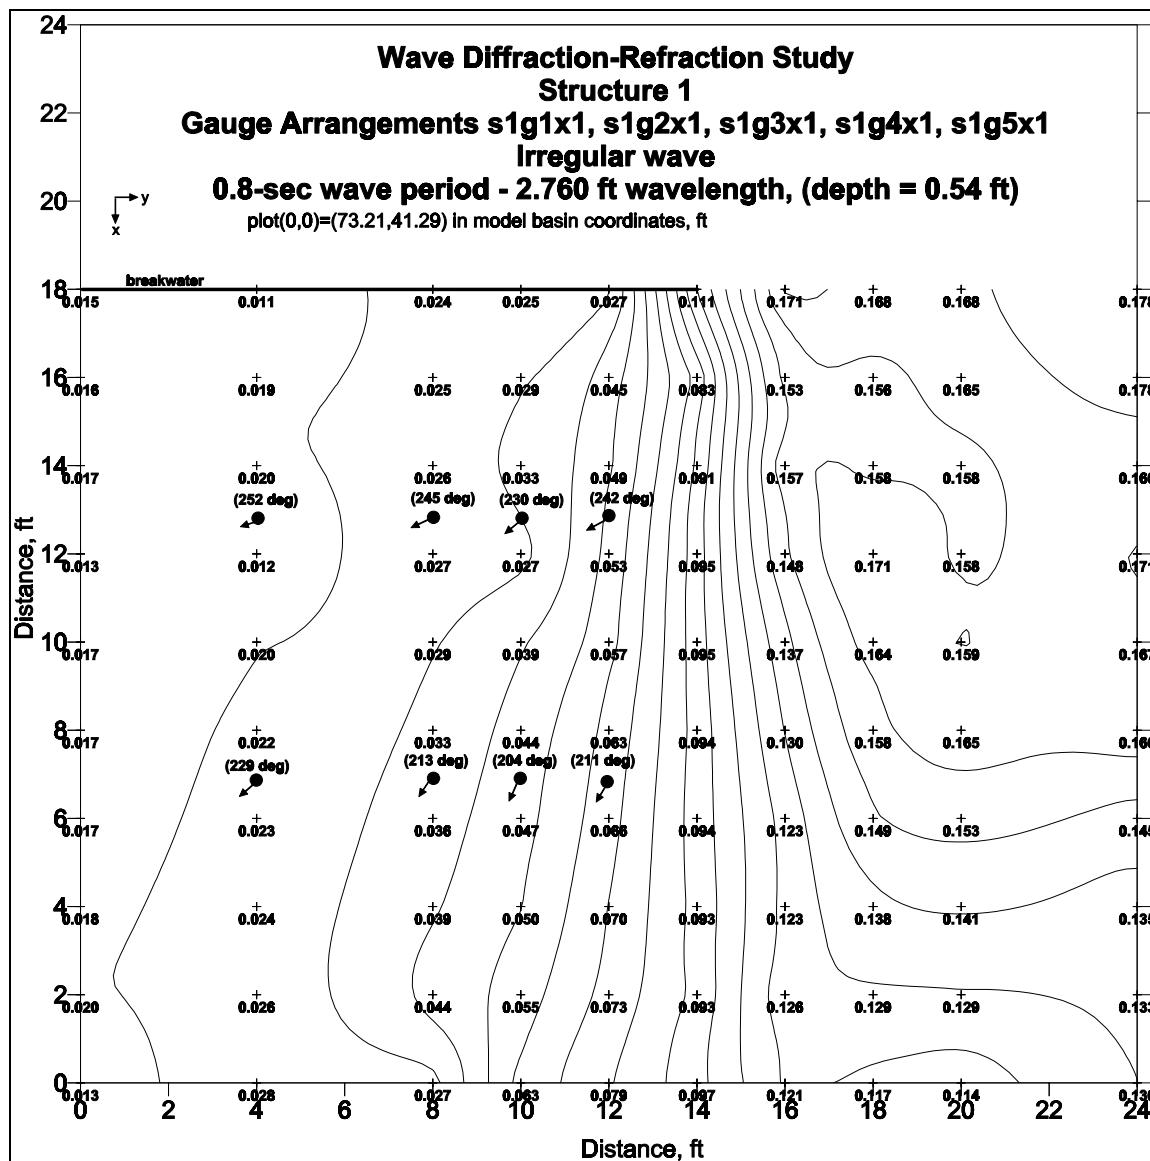

Figure 15. Contoured plot of wave height transformation for Structure 1, Experiment 1 (gauge arrangements 1 through 5). Wave period is 0.8 sec, wave approach 0 deg (perpendicular to the breakwater) for this irregular wave case. Contour interval is 0.30 cm (0.01 ft). Arrows show peak wave direction acquired at peak period

Structure 2

The Structure 2 configuration was similar to that of Structure 1, but in place of the shore-parallel breakwater, it contained one dogleg jetty with the inner segment perpendicular to the shore (Figure 7). A total of six experimental conditions were studied, as noted in Table 2. For an incident wave direction of 0.0 deg, irregular waves of 0.8 sec, 6.1 cm (0.2 ft), and 1.6 sec, 4.6 cm (0.15 ft), and monochromatic waves of 0.8 sec, 4.6 cm (0.15 ft), were produced. The wave generator was repositioned for a 20-deg incident wave direction and the same three wave conditions were repeated. The 20-deg angle was oriented such that less energy would be propagated behind the breakwater.

The tables in Appendix D contain gauge number, depth at the gauge, average water surface elevation relative to the still-water level, significant wave period, significant wave height, average wave height, and maximum wave height. The data are in tables for each gauge arrangement, as shown and noted in Figure 8. Appendix E presents contoured dimensional wave height plots. Figure 16 shows the 0.8-sec wave experiment wave-height contours and wave direction from the velocity gauges. The x-y arrows in the plots indicate the basin x-y position that corresponds to the plot origin (0.0). Appendix J contains sample spectral energy density versus frequency plots for selected wave gauge locations. The overall basin bathymetry, the shore-parallel breakwater structure, the dogleg jetty structure, and the parallel jetties structure are referenced in Appendix K. Due to the large volume of data, it has been placed on the accompanying CD. The location of wave gauges and the dogleg jetty within the coordinate system is given in Appendix M.

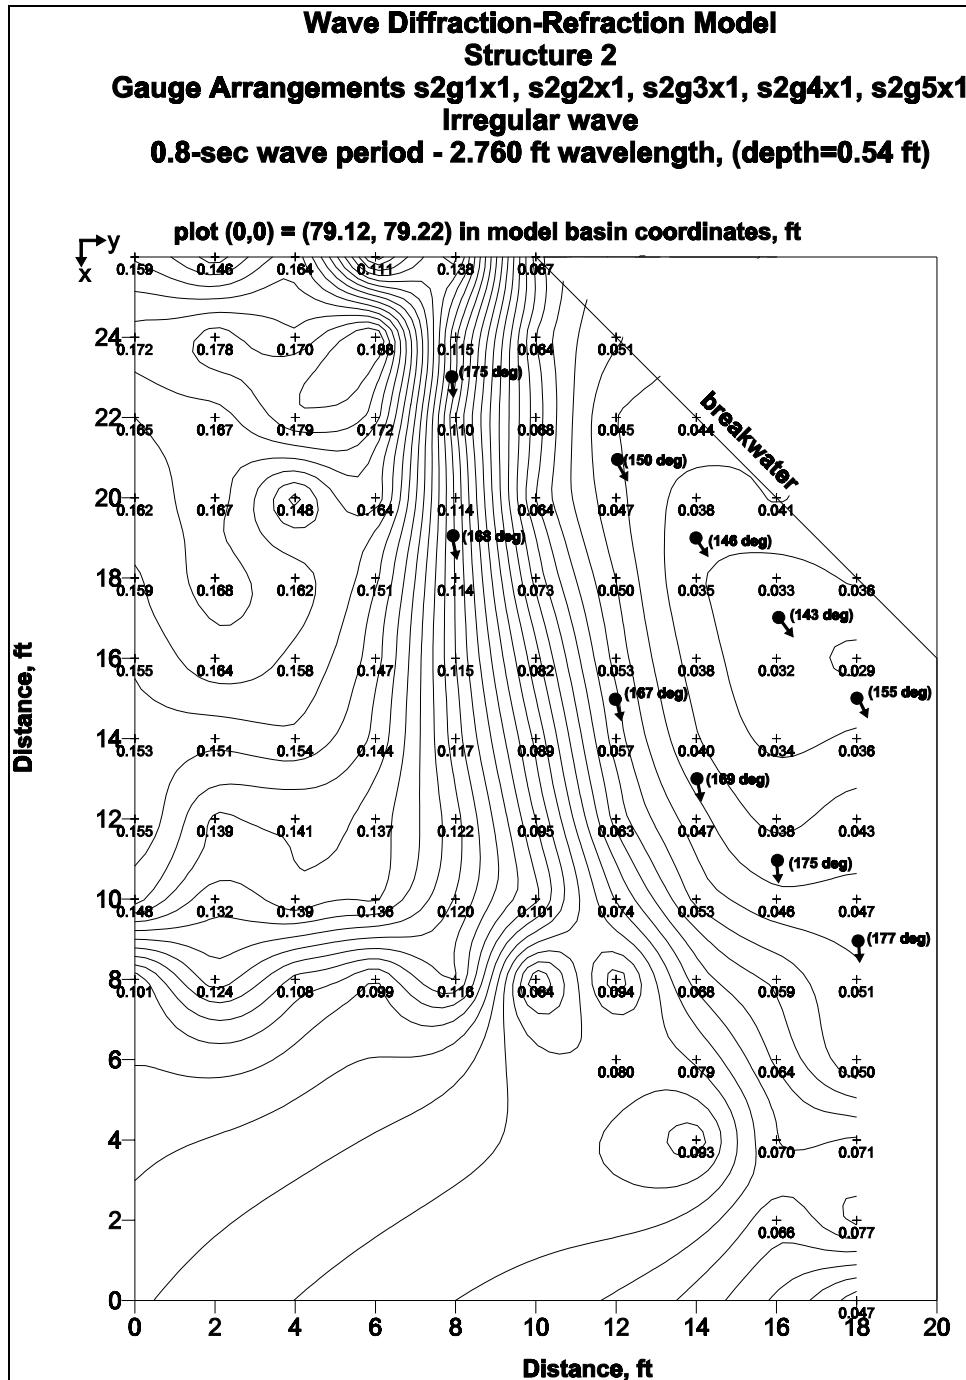

Figure 16. Contoured plot of wave height transformation for Structure 2, Experiment 1 (gauge arrangements 1 through 5). Wave period is 0.8 sec, wave approach 0 deg for this irregular wave case. Contour interval is 0.03 m (0.01 ft). Arrows show peak wave direction acquired at peak period

Structure 3

The Structure 3 configuration contained no jetties, and was designed to simulate diffraction through a gap, such as shown in Figure 1. The placement of the gauges was bayward (see Figure 11), as opposed to seaward, as with the Structure 1 and 2 configurations. For some of these experiments, the physical model was arranged to produce a flood current as discussed in Chapter 2. The wave direction remained perpendicular to the shoreline, 0 deg, throughout the testing sequence. A total of six experimental conditions were studied, as noted in Table 2. For no-flood current conditions (Chapter 2), irregular waves of 0.8 sec, 6.1 cm (0.2 ft), and 1.6 sec, 4.6 cm (0.15 ft), and monochromatic waves of 0.8 sec, 4.6 cm (0.15 ft), were produced. The flood current conditions were created and the same three wave conditions were repeated. Appendix F contains data tables for the gauge arrangement, shown in Figure 9, for each experiment.

The tables contain gauge number, depth at the gauge, average water surface elevation relative to the still-water level, significant wave period, significant wave height, average wave height, and maximum wave height. Appendix G presents contoured dimensional wave height plots. Figure 17 shows the 0.8-sec wave experiment wave height contours and wave direction from the velocity gauges. The x-y arrows depicted on the plots indicate the basin x-y position that corresponds to the plot origin (0,0). Appendix J contains sample spectral energy density versus frequency plots for selected wave gauge locations. The overall basin bathymetry, the shore-parallel breakwater structure, the dogleg jetty structure, and the parallel jetties structure are referenced in Appendix K. Due to the large volume of data, it has been placed on the accompanying CD. The location of wave gauges within the coordinate system is given in Appendix N.

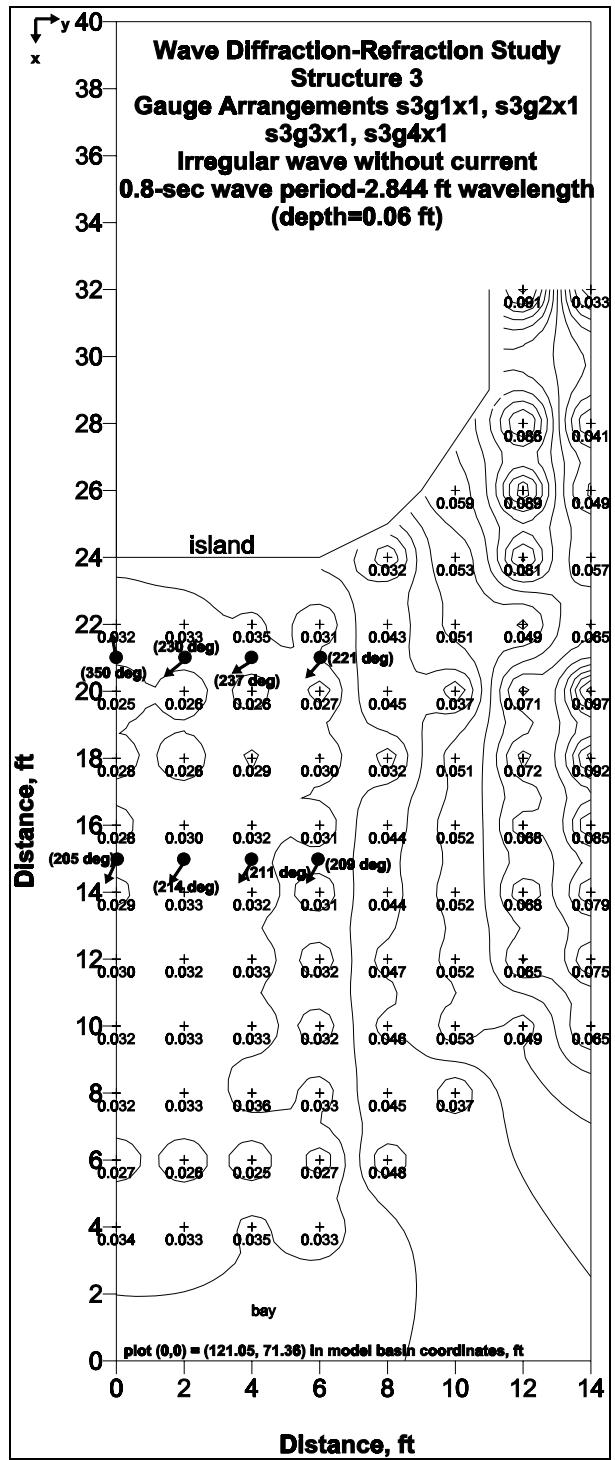

Figure 17. Contoured plot of wave height transformation for Structure 3, Experiment 1 (gauge arrangements 1 through 4). Wave period is 0.8 sec, flood current off, wave approach 0 deg (perpendicular to shoreline) for this irregular wave case. Contour interval is 0.30 cm (0.01 ft). Arrows show peak wave direction acquired at peak period

Structure 4

The Structure 4 configuration consisted of two jetties perpendicular to shore. The placement of the gauges was bayward (Figure 12) as opposed to seaward as with the Structure 1 and 2 configurations. A total of four experimental conditions were studied, as noted in Table 2. For no-flood current conditions (Chapter 2), irregular waves of 0.8 sec, 6.1 cm (0.2 ft), and 1.6 sec, 4.6 cm (0.15 ft), and monochromatic waves of 0.8 sec, 4.6 cm (0.15 ft), were produced. The flood current conditions were created and the same irregular wave, 1.6 sec, 4.6 cm (0.15 ft), was repeated. Appendix H contains data tables for the gauge arrangement, shown in Figure 10, for each experiment.

The tables contain gauge number, depth at the gauge, average water surface elevation relative to the still-water level, significant wave period, significant wave height, average wave height, and maximum wave height. Appendix I presents contoured dimensional wave height plots. Figure 18 shows the 0.8-sec wave experiment. The x-y arrows depicted on the plots indicate the basin x-y position that corresponds to the plot origin (0.0). Appendix J contains sample spectral energy density versus frequency plots for selected wave gauge locations. The overall basin bathymetry, the shore-parallel breakwater structure, the dogleg jetty structure, and the parallel jetties structure are referenced in Appendix K. Due to the large volume of data, it has been placed on the accompanying CD. The location of wave gauges and the parallel jetties within the coordinate system is given in Appendix O.

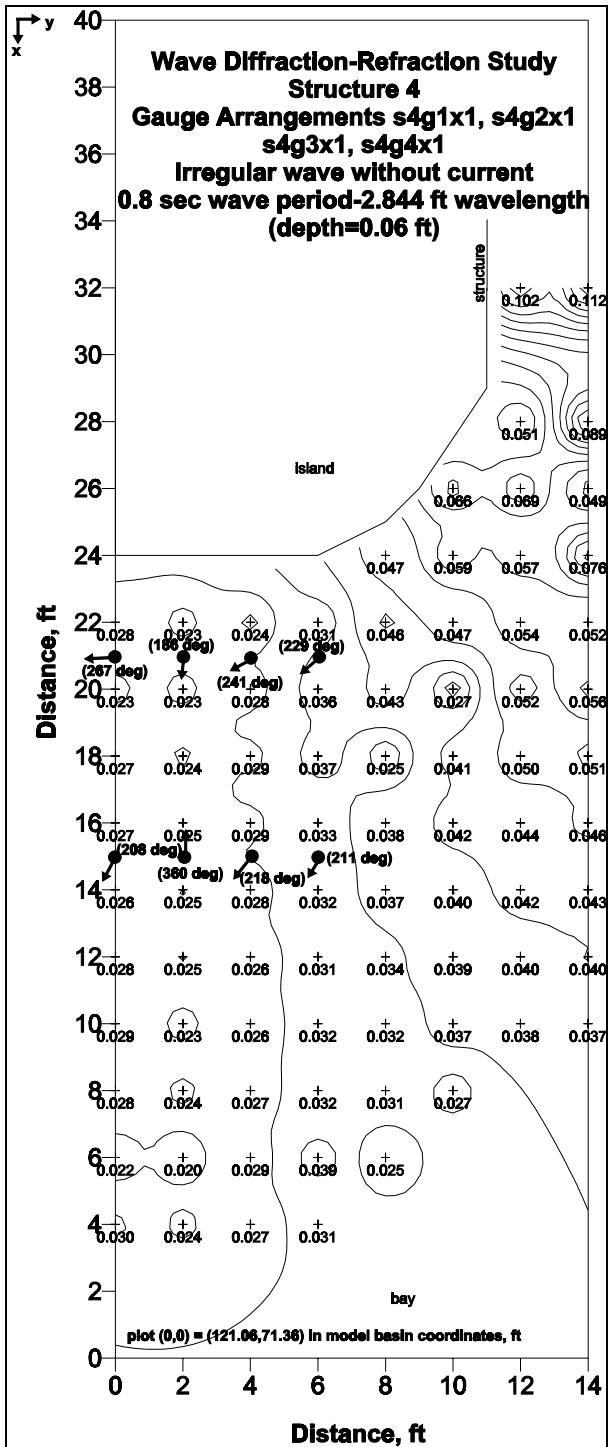

Figure 18. Contoured plot of wave height transformation for Structure 4, Experiment 1 (gauge arrangements 1 through 4). Wave period is 0.8 sec, flood current off, wave approach 0 deg (perpendicular to shoreline) for this irregular wave case. Contour interval is 0.30 cm (0.01 ft). 5 Video-Based Wave Direction Measurement

This chapter discusses the need for implementing a video-based wave direction measurement system in the physical model setting and describes procedures followed for making these measurements. Results from the video-based analysis for each experiment conducted in the idealized coastal inlet physical model are presented.

Background

In the physical model setting, the primary diagnostic tools to investigate the complex interaction of incident wind-waves with variations in inlet bathymetry, engineered inlet structures, and tidal currents are capacitive wave rods and ADV probes. These instruments are deployed at discrete locations to measure wave height and current fields. A disadvantage of the application of wave rods and ADV probes is that they are intrusive and cause localized disturbance in the fluid motions of the model. To minimize these undesired perturbations, CIRP implemented a video-based nonintrusive technique to measure wave parameters accurately with high spatial and temporal resolution. This technique is called the Coastal Inlets Imaging System (CIIS). Specifically, the CIIS provides measurements of vector-mean wave direction of wind-wave fields with time- and space-varying scales observed on the free surface of the model. Measurements obtained with the CIIS have broad application and can provide quantitative information for understanding basic coastal inlet process and supporting computational model development and validation.

During the past decade, video techniques have been developed and applied in the coastal region to measure variations in hydrodynamic processes (Hathaway and Bottin 1997; Holland, Holman, and Sallenger 1991; Holland et al. 1995; Holland and Holman 1996; Holland and Holman 1999; Lippmann and Holman 1991; Stockdon and Holman 2000) and morphologic processes (Konicki and Holman 2000; Lippmann and Holman 1990; Lippmann, Holman, and Hathaway 1993; Plant and Holman 1997; Ruessink et al. 2000). Development of the CIIS builds on these photogrammetric and image-processing techniques developed by the Argus Research Program coordinated by the Coastal Imaging Lab, Oregon State University (Holman et al. 1993; Aarninkhof and Holman 1999). The physical model video system consists of obliquely looking monoscopic camera stations mounted at vantage points above the physical model. Lens distortions,

camera locations, and ground control coordinates are measured to establish a geometric model relating phenomena observed in two-dimensional (2-D) image coordinates (u, v) to the physical model's three-dimensional (3-D) x -, y -, z - coordinate system via a direct linear transformation. Figure 19 shows the geometric relationship between an object observed in image space and in object space. The capability to transform accurately between image and object space enables the CIIS to operate as a measurement system. Holland et al. (1997) gives a comprehensive treatise on the mathematics of the camera calibration (lens distortion correction) and application of photogrammetric methods.

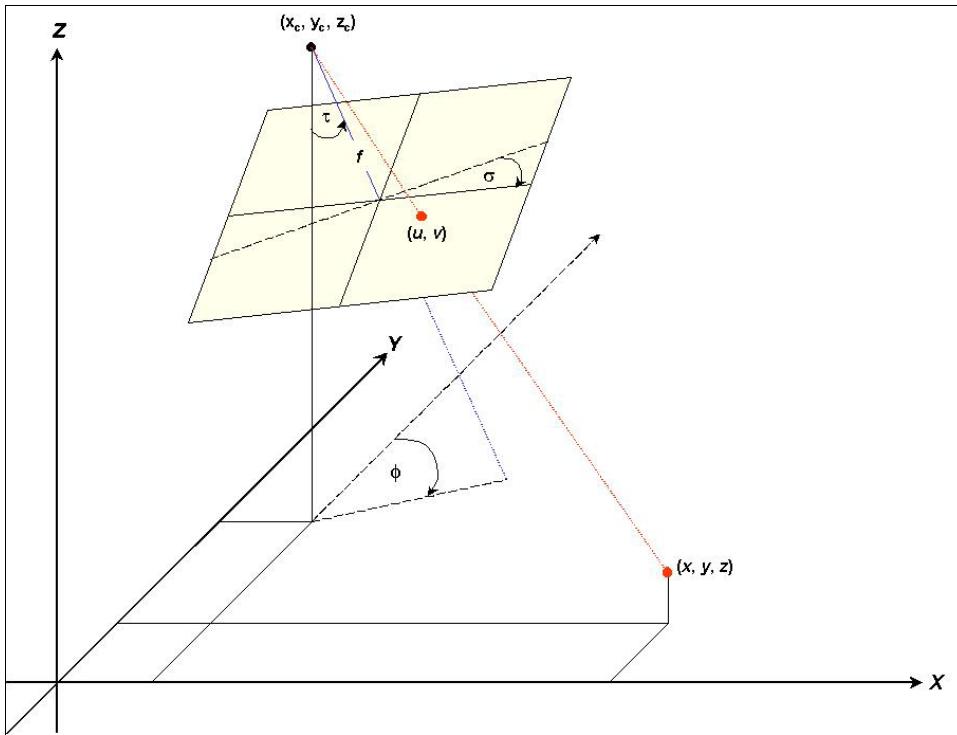

Figure 19. Geometric relationship between the camera (x_c, y_c, z_c) , the object of interest observed on the image plane (u, v) and in real-world coordinates (x, y, z) , angles of camera rotation (τ, σ, ϕ) , and the camera focal length (f) (after Holland et al. 1997)

The general premise for video-based wave direction measurement in the physical model is as follows. Diffuse lamps create a directional gradient of light over the model. As waves propagate by a fixed point on the free surface, the intensity of directional specular reflection from the surface of the wave slope varies from light to dark. The degree of variation depends on the viewing angle relative to the direction of wave propagation and illumination. A vertical camera angle observes a field of high- and low-intensity bands over the free surface as waves propagate toward the source illumination. That is, the forward face of the wave has a higher intensity signature than the back face of the wave shadowed by the front. These temporal and spatial variations in light intensity are observed by a camera and recorded on videotape. The signals are digitized and analyzed to

determine the relationship between the phase structures (time lag) of light intensity time series records measured at specified locations within the field of view of the camera. It is assumed that the physical relationship between the visual signature of the wave in image space and the true wave in object space is spatially constant.

Equipment Installation and Experiment Preparation

The data acquisition component of the CIIS comprises several commercially available video components. Synchronized SonyTM SSC-54A color video charge-coupled device cameras are mounted at vantage points above the physical model on support beams. Synchronization of the cameras is required for simultaneous data acquisition from each camera view. Manual iris NavitarTM lenses with focal lengths of 8 and 6mm provide the desired degree of spatial resolution. Figures 20 and 21 show pixel resolutions for a typical imaged area in the physical model for camera stations located 3.8 m (12.5 ft) above the free surface for the 8 and 6mm lenses, respectively. For example purposes, the cameras are located arbitrarily in a rectilinear coordinate system. The 8mm lens-camera combination is oriented with a tilt angle of 55 deg off nadir and a roll angle of 0 deg, and it has a horizontal field of view of 40 deg. This camera orientation results in < 2-cm pixel resolution in the direction perpendicular to the camera azimuth over the entire imaged area. Pixel footprints in the direction of the camera azimuth are highly resolved in both the near and far fields (< 4 cm). The 6mm lens-camera combination has a tilt angle of 48 deg, a roll angle of 0 deg, and a horizontal field of view of 54.6 deg. The shorter focal length provides a wider field of view and slightly lower resolution. Cross-azimuth pixel resolution is < 2 cm over the imaged area, and along-azimuth resolution is < 4 cm.

Camera-lens combinations are calibrated at the Field Research Facility, Duck, NC, Coastal and Hydraulics Laboratory, U.S. Army Engineer Research and Development Center, to determine lens distortion coefficients and optical characteristics of a given camera-lens combination prior to installation. Cameras identified as 1 and 2 in this report have 6mm focal length lenses, and cameras identified as 3 through 6 have 8mm lenses. Each camera is connected to a PanasonicTM AG-1980P videocassette recorder (VCR) via BeldenTM 8281F composite video cable. Super Video Home SystemTM (SVHS) cable is desired for increased videotape resolution; however, long cable lengths between cameras and VCRs (>30 m) dictated the use of composite video cable to prevent loss of signal strength. The video signal from each camera passes through a synchronized HoritaTM vertical interval time code (VITC) generator before being recorded by the VCR at a frame rate of 30 Hz. VITC time code is recorded on each video frame to allow identification of a specific frame of interest during VCR playback and image digitization.

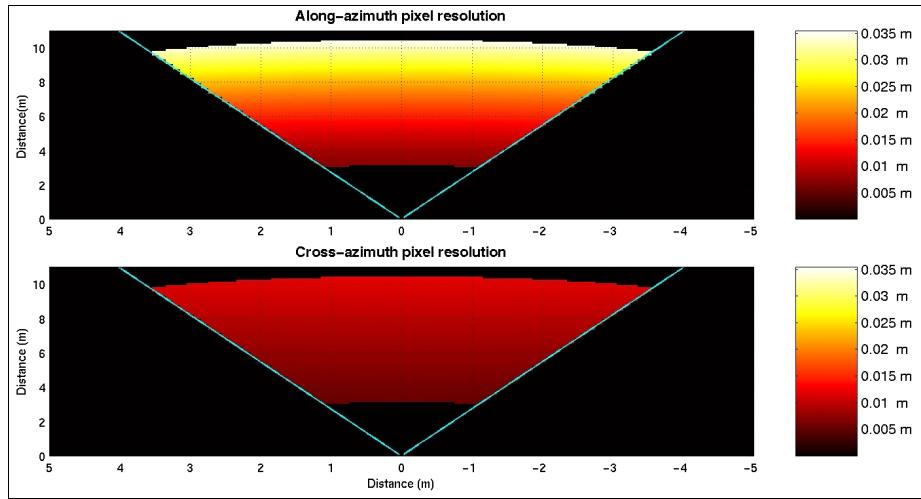

Figure 20. Example pixel resolution for 8 mm focal length

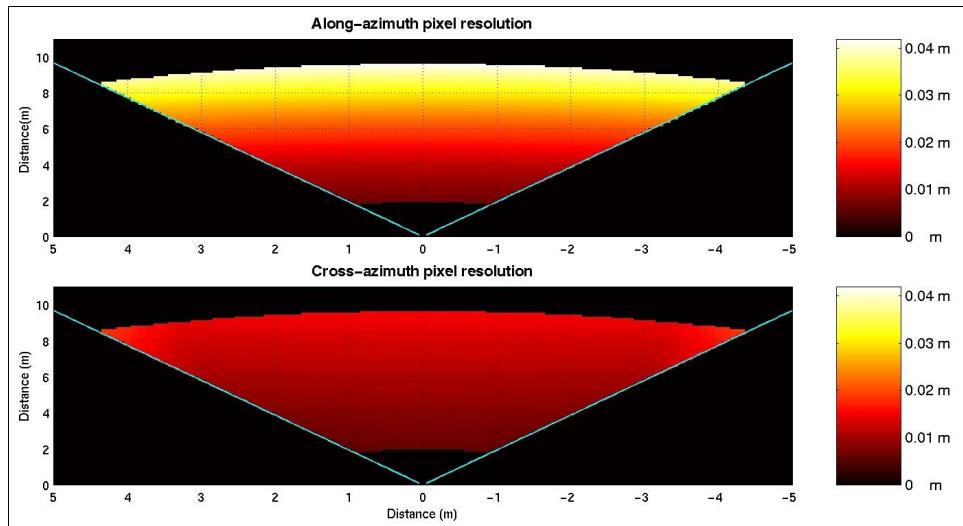

Figure 21. Example pixel resolution for 6mm focal length

Following equipment installation, horizontal and vertical coordinates of the camera locations and ground control points (GCPs) are surveyed with a total survey station. GCPs are landmarks observed in a camera view that have known object space and image space coordinates. For the series of physical model experiments conducted, GCPs consisted of tick marks painted on the varying bathymetry of the model. Figure 22 shows example GCPs for the Structure 3 and 4 experiments. Survey data, lens distortion corrections, image digitizer information, and a video snapshot of the drained physical model determined geometry solutions for each camera view. A geometry solution can be determined for each camera view with as few as two GCPs. However, more GCPs allow for a least-squares solution with minimal error. For each physical model configuration (i.e., Structures 1 through 4), cameras were reoriented to provide a field of view of the desired measurement area. A geometry solution was calculated for each camera orientation and stored in a database for access by the image processor and coordinate transformation algorithms. Structures 3 and 4 had the same camera orientation, eliminating recalculation of camera geometry.

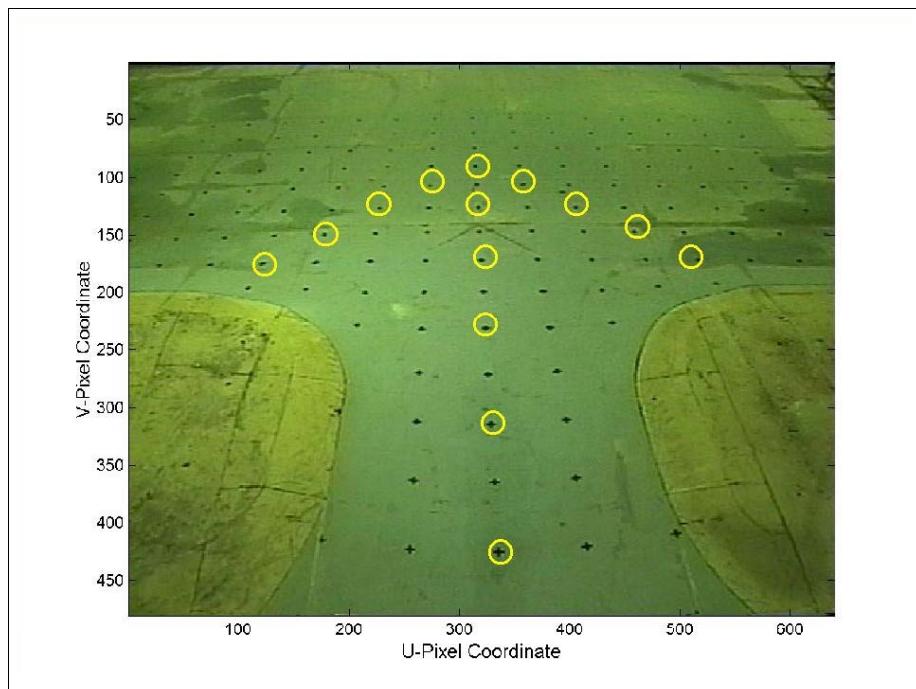

Figure 22. Structures 3 and 4 C1 camera view. GCP locations used for view geometry solution are circled

Diffuse incandescent lamps are positioned to illuminate the waves over an area of interest on the free surface in a manner to create a clearly visible signature of the wave field by the camera. Care is taken to prepare the area around and above the physical model to minimize undesired shadows and illumination within the field of view. During the testing phase of CIIS development, it was observed that the model illumination was refracted through the water column onto the model bathymetry. The refracted high-intensity bands dominated the video signal and degraded the phase structure of the observed

surface wave signal (Figure 23). To prevent the light refraction through the water column and to increase the strength of the desired signal, Sphericel™ hollow glass spheres were distributed throughout the water column (Figure 24). The spheres have the appearance of a white powder and a range of specific gravity of 0.1-1.5 g/cc. During wave generation, distribution of white pigmentation in the water column remains well mixed.

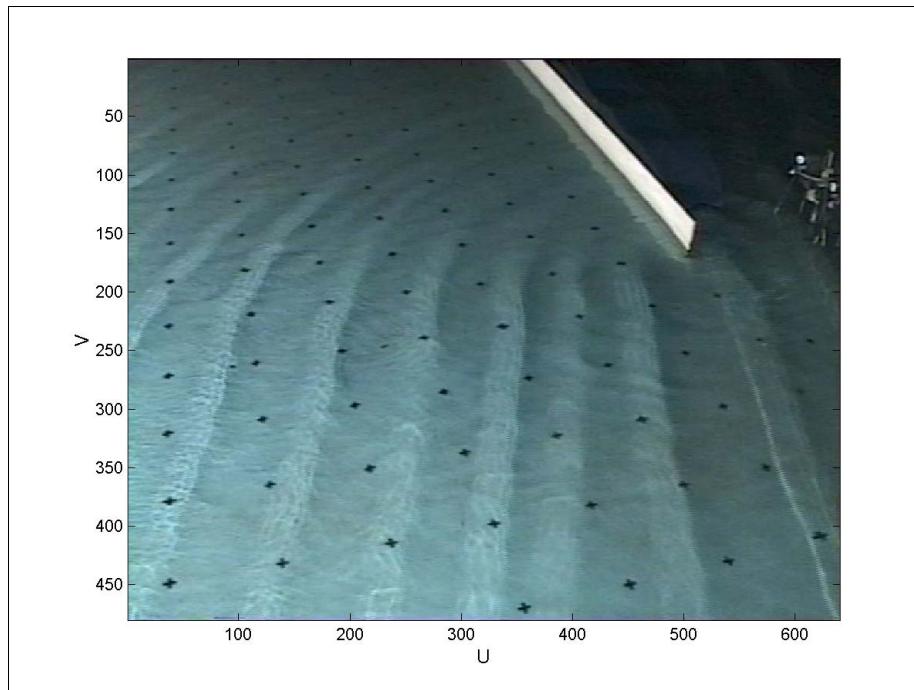

Figure 23. Structure 1, Experiment 1, Camera 4 video snapshot demonstrating undesired high-intensity signals and gradients in light intensity between wave crests caused by light refraction through the clear water column onto the model bathymetry, and reflection of light from the engineered structure

Structure 1, Experiments 1 through 3, were conducted before the application of the pigmentation to the physical model. Although video data were collected during Structure 1, Experiments 1 through 3, analysis is not presented due to poor signal quality. All other experiments conducted for Structures 1 through 4 included application of the pigment.

Data Acquisition and Analysis Procedures

Sampling design

For each experiment, an idealized field of virtual wave gauge arrays was designed to provide estimates of mean wave direction at high spatial resolution within the physical model. Based upon the generated target spectra and mean model water depth, an 0.8- by 0.8-m aperture cross-shaped array was designed to

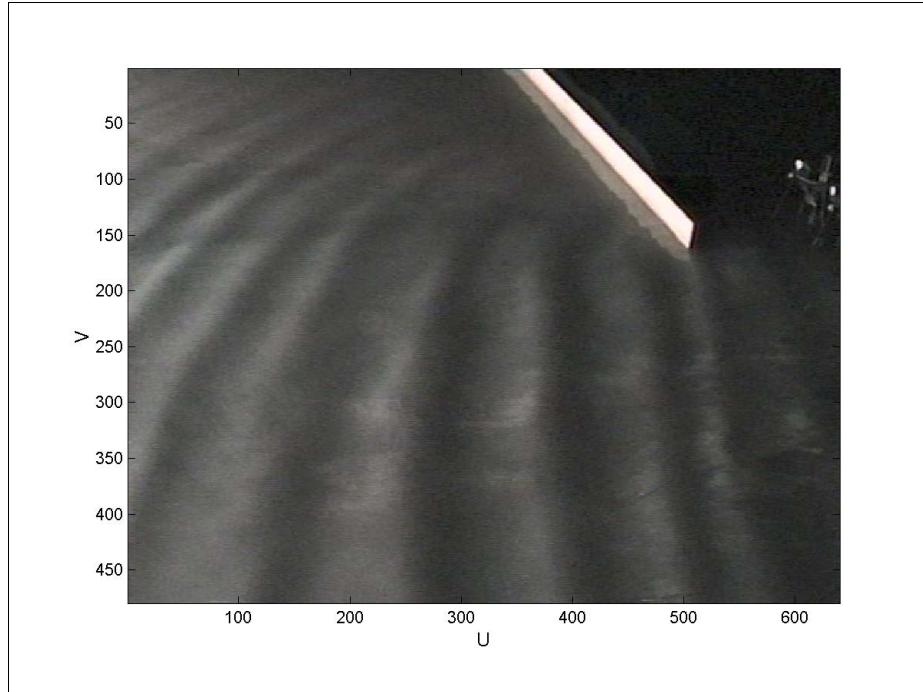

Figure 24. Structure 1, Experiment 4, Camera 4 video snapshot demonstrating the use of white pigment to eliminate refraction of light through the water column. High-intensity bands are the illuminated forward-facing surface wave slopes

optimize measurement of expected wavelengths (Figure 25). The array orientation resulted in 39 independent lag distances between all possible combinations of sensor locations. The wave phenomena of interest exist in a 3-D physical model coordinate system. However, the waves are observed with a 2-D video image. Image coordinates cannot be transformed to physical model coordinates since the problem is underdetermined. To solve the problem of coordinate transformation, information in addition to the camera geometry solution must be known. For the video application herein, the additional information required was the physical model still-water level (swl). Assuming that the pixel array sampling elements are located on the free surface of the physical model, the location of the swl and the camera geometry solution are combined to make the transformation between the 2-D and 3-D coordinate systems. Thus, each array element has a unique xy-coordinate and a common z-coordinate equivalent to swl in the physical model reference frame.

Pixel arrays are located to cover the region of interest in each camera view. Figures 26 through 32 show the superposition of the elements (+) of each pixel array for each camera view and model configuration. Open circles indicate array analysis output locations, and solid circles indicate collocated ADV-CIIS measurement locations. The number of pixel sampling elements for time series collection is described in Table 5.

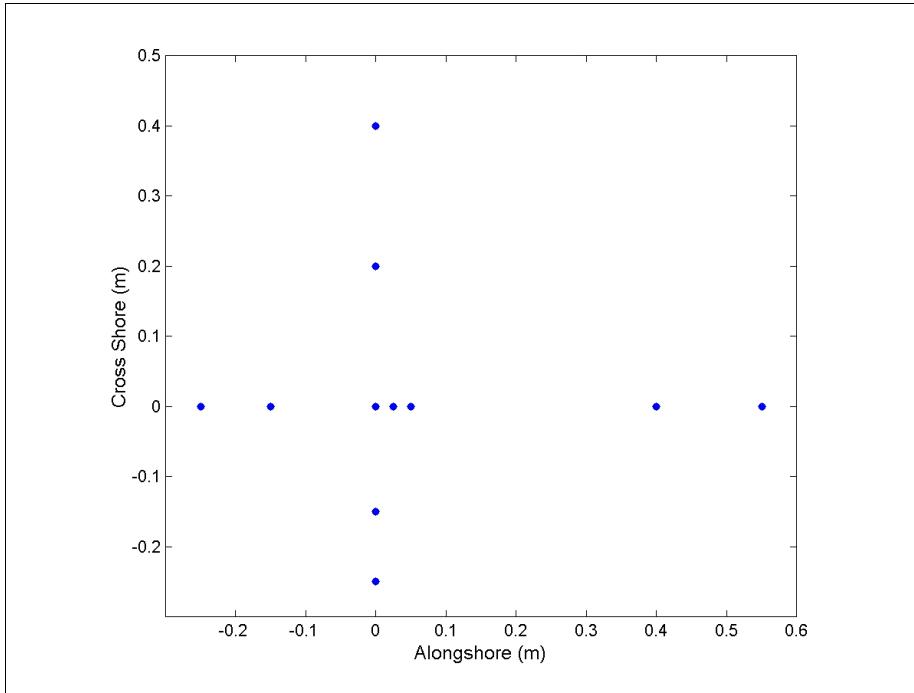

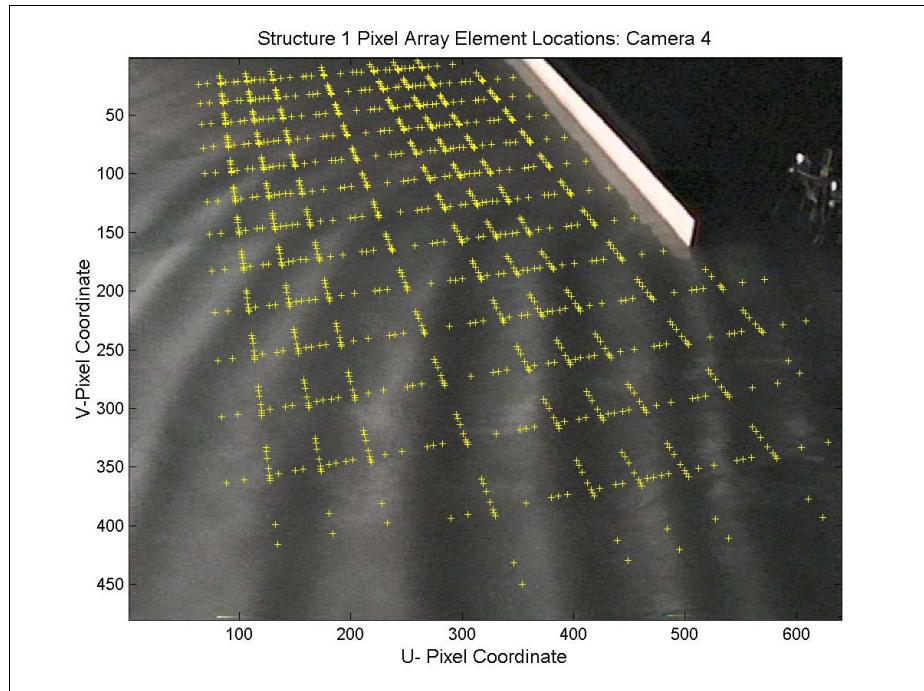

Figure 25. 0.8- by 0.8-m-aperture cross-shaped pixel sampling array orientation and pixel sensor spacing

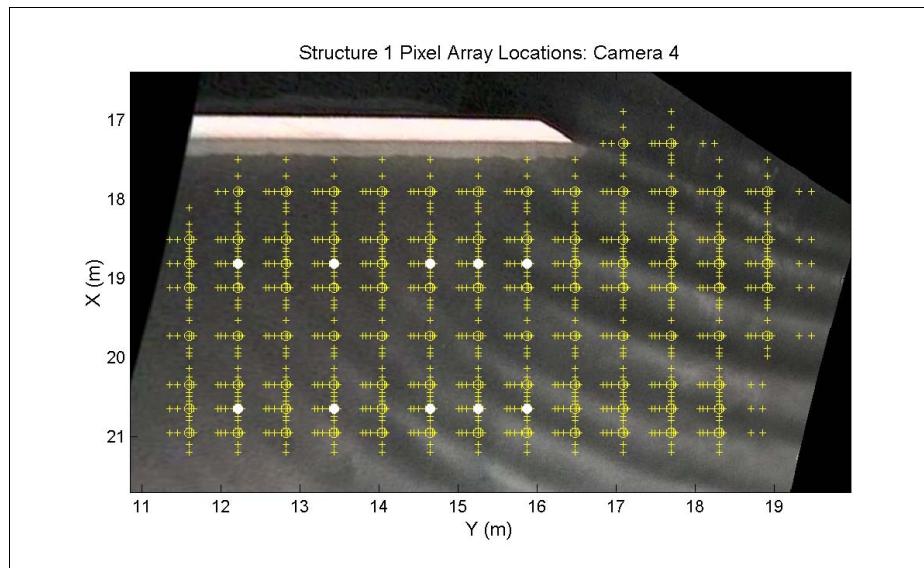

For Structure 1, the two camera views overlap slightly resulting in 20 collocated CIIS arrays. The combination of the two views results in 82 video-based directional measurement locations. The Structure 2 experiment arrangement required four camera views to cover the measurement area of interest. Arrays are regularly spaced in a 0.3-m grid. Edges of the camera views overlap slightly, resulting in 72 collocated CIIS arrays. Combination of the Structure 2 camera views produces 481 video-based directional measurement locations. For the Structure 3 and 4 arrangements, a single camera view was required to observe the measurement area. Arrays are regularly spaced at 0.3-m intervals, giving 305 measurement locations. Sampling elements are located on only one-half of the diffraction region, because it is assumed that diffraction patterns are symmetric in the bay for this model configuration.

Image processing

Recorded video of the wave experiment is played back to the image processor for digitization. The platform for the image processing software is a Silicon Graphics Inc™ R5000 video workstation. The highest frequency that can be defined by the CIIS sampling rate of 30 Hz is 15 Hz. Frequency content above 15 Hz in the original signal will be aliased or “folded” into the frequency range between 0 and 15 Hz. Because the high-frequency limits of the target spectra were sufficiently lower (<70 percent) than the band limiting frequency,

Structure 4	C1	3355	305	NA

no effort was made to remove information contained in the original analog signals. During the playback process, the image processor collects time series records of pixel intensity at locations corresponding to measurement array elements. The software reads VITC on each video frame to locate the image records of interest.

Pixel intensity time series records are called timestacks. Pixel intensities are recorded as unsigned numerical representatives of gray values ranging from 0 (dark) to 255 (bright). Figure 33 shows an example timestack collected at a sample rate of 30 Hz for duration of 10 sec during a random wave test. Bright regions of the timestack are associated with the wave crest and wave slope facing the illumination source. Dark regions of the timestack are associated with the wave trough and slope of the wave facing away from the illumination in the shadow of the wave.

Time series analysis

As previously mentioned, the premise for use of CIIS as a wave direction measurement system is that, for waves propagating past a fixed point on the free surface, the intensity of directional specular reflection from the surface of the wave slope varies from light to dark. It is assumed that, outside of the wave-breaking region, the phase structure of the timestacks is a proxy for the phase structure of the true propagating wave signal. To exemplify this assumption, Figure 34 shows synchronized time series records of reflected light intensity and wave height from a collocated pixel sampling element and capacitive wave rod. These measurements were obtained during a Structure 4 monochromatic wave test in the diffraction region, and temporal variations from peak to trough are strongly correlated.

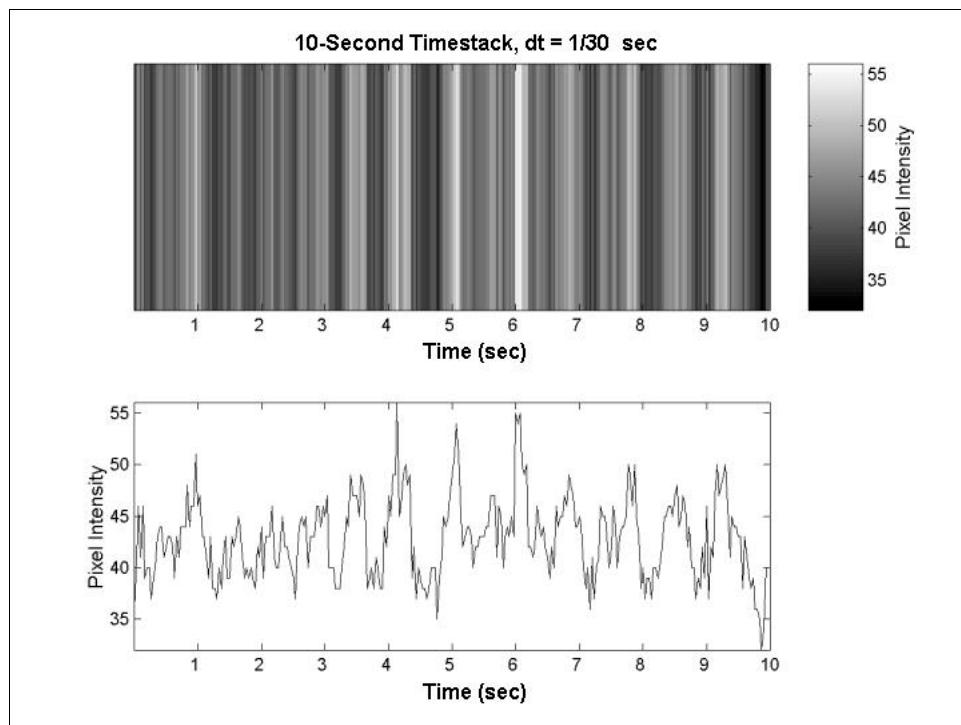

Figure 33. Example 10-sec-duration timestack recorded in the diffraction region during the Structure 4 monochromatic wave experiment

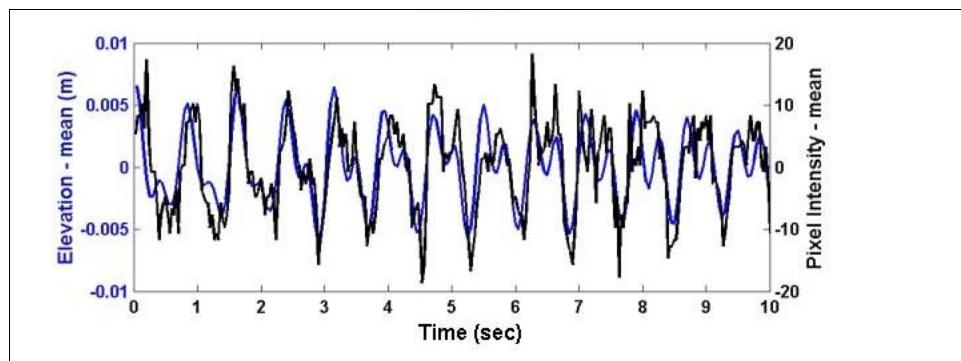

Figure 34. Example 10-sec time series records measured by collocated capacitive wave rod and pixel sampling element in the diffraction region during the Structure 4 monochromatic wave experiment

Timestacks are analyzed to provide estimates of vector-mean wave direction $\theta_m(f)$. Directions are derived from the phase difference between the signals measured at one location relative to the signal at another for all array elements. Figure 35 shows a visual example of the phase structure observed by the alongshore elements of a pixel array during a random wave test for a duration of 10 sec. Focusing on the record between 3 and 4 sec, the slight temporal offset of the low intensity between sampling locations is indicative of a wave propagating obliquely through the array. With the separation distance between elements of a pixel array known in real-world coordinates, timestacks are analyzed in terms of an estimated root-mean-square average wave number $k_{rms}(f)$ following Herbers, Elgar, and Guza (1995). This method is based on an expansion of the theoretical cross-spectrum of gravity waves for small sensor separations relative to wavelength. The computed wave number moments are extended to calculations of alongshore and cross-shore components of wave number $k_y(f)$ and $k_x(f)$ by linear combination of normalized quadspectra:

$$k_x = \sum_{p=1}^N \sum_{q=1}^N \alpha_{pq} \frac{Q_{pq}(f)}{\sqrt{P_{pp}(f)P_{qq}(f)}} \quad (2)$$

where

Q_{pq} = quad-spectrum of pixel sensor pair locations in 3-D coordinate system $[x_p, y_p]$ and $[x_q, y_q]$

N = number of array elements

P_{pp} and P_{qq} = autospectra for pixels sensors located at $[x_p, y_p]$ and $[x_q, y_q]$

Least-squares fit solutions of wave number coefficients α_{pq} are obtained by singular value decomposition of

$$\sum_{p=1}^N \sum_{q=1}^N \alpha_{pq} i^n \frac{(x_p - x_q)^{n-m} (y_p - y_q)^m}{(n-m)! m!} = 1 \quad (3)$$

for $n = 2, m = 0$ and $n = 2, m = 1$, and

$$\sum_{p=1}^N \sum_{q=1}^N \alpha_{pq} i^n \frac{(x_p - x_q)^{n-m} (y_p - y_q)^m}{(n-m)! m!} = 0 \quad (4)$$

for n and $m = \text{other}$ and $i^n = \sqrt{-1}$. The number of terms in the expansion was constrained to 8, and the truncation value for the smallest eigenvalue (relative to the largest eigenvalue) was 10^{-4} .

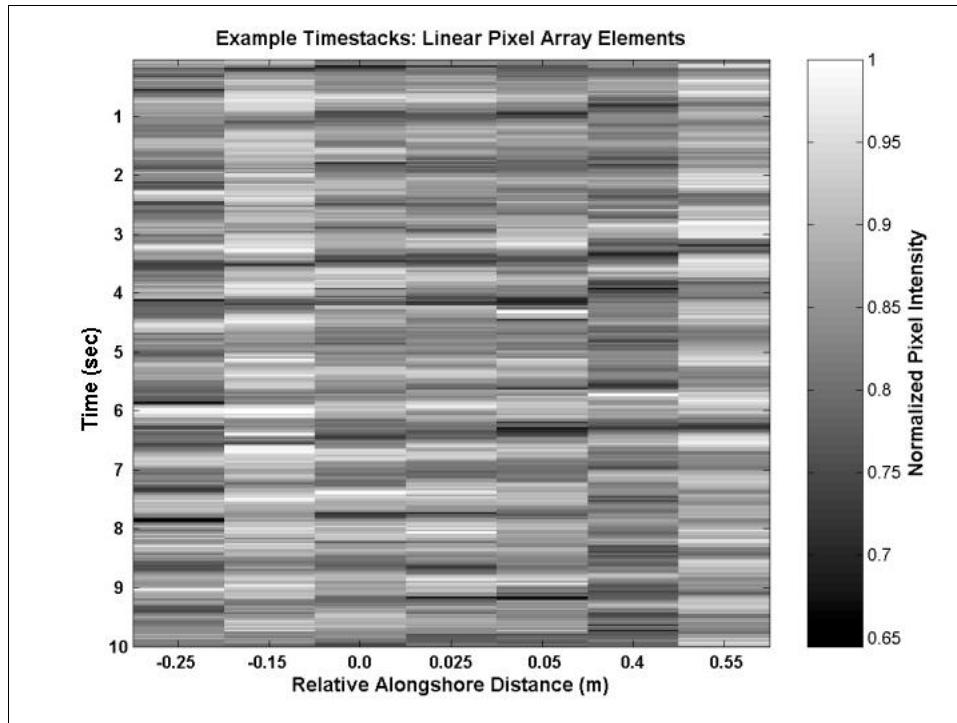

Figure 35. Example 10-sec normalized timestacks obtained from the alongshore elements of a cross-shaped array during a spectral wave experiment

Estimates of the normalized cospectra and quadsspectra are obtained from Fourier transforms of sensor pair timestacks. Each timestack is 7 min in duration and consists of 12,600 samples. To improve computational performance, frequencies above 3 Hz were not considered for analysis. Timestacks were linearly detrended, tapered, and divided into six ensembles of 2,048 samples and band averaged resulting in a frequency resolution of 0.0439 Hz and 36 deg of freedom.

With each physical model configuration (Structure) and generated wave spectrum (Experiment), the direction region represented a broad range of wave heights. In addition, a gradient in light illuminated the measurement areas. Therefore, noisy pixel intensity signals and low coherence between sampling elements of pixel arrays were anticipated. For example, low-amplitude and low-variance pixel intensity fluctuations may be observed across a poorly illuminated array. Conversely, high pixel intensity and low variance may be observed across array elements in brightly lit areas. The coherence-squared function was calculated for all possible gauge pairings in an array. To avoid spurious results in the calculation of $\theta_m(f)$, a coherence-squared threshold amplitude value of 0.7 was arbitrarily selected. Coherence-squared estimates equal to or above the threshold value indicate meaningful coherence between array element pairings. Only frequency content of array pairings with meaningful coherences was accepted to calculate estimates of $\theta_m(f)$ with reliability. Estimates of $\theta_m(f)$ meeting the coherence cutoff criteria are typically at or near the spectral peak.

Validation

Video measurements of $\theta_m(f)$ are validated against collocated in situ ADV probe measurements. ADV observations of horizontal velocity components were sampled at a rate of 20 Hz for a duration of 204.8 sec, resulting in 4,096 samples. Time series records were linearly detrended, tapered, and ensemble averaged resulting in a frequency resolution of 0.078 Hz and 32 deg of freedom with a maximum frequency cutoff of 5 Hz.

To facilitate comparison, ADV energy density and direction values were interpolated using a piecewise cubic Hermite interpolation within the frequency bands observed by the video system. Superimposed on the rectified (lower) images shown in Figures 26, 27, 29, 31, and 32 are solid circles that represent ADV and CIIS measurement collocations. Figure 36 is a representative graphical comparison of normalized energy density and direction versus frequency at a single measurement location for a random wave experiment ($f_{peak} = 1.25$ Hz). The peak spectral density for graphical comparison normalizes the variance spectrum. For visual reference, Appendix P presents a graphical comparison of energy density and mean direction versus frequency for each Structure 1 collocated CIIS-ADV location.

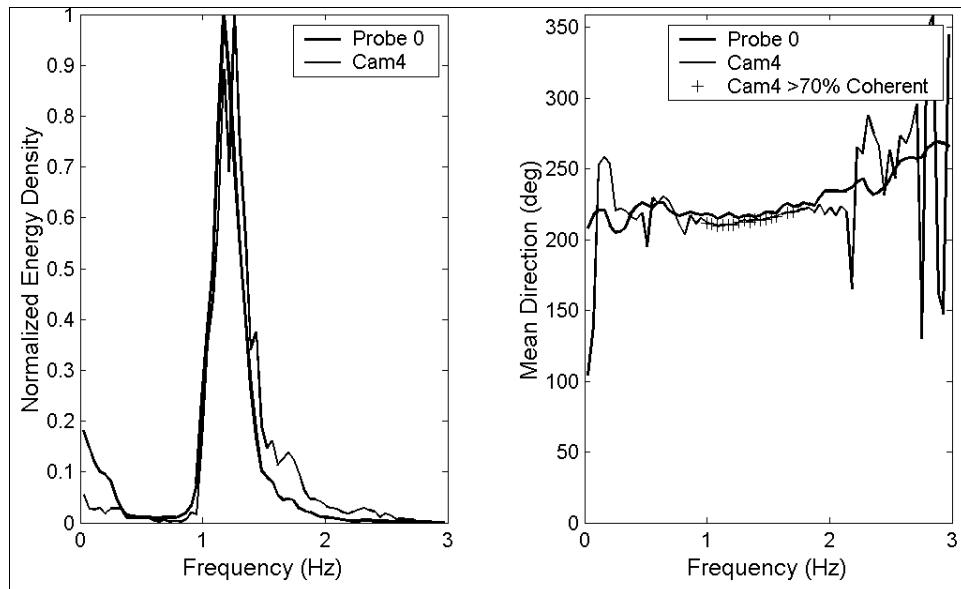

Figure 36. Representative collocated video-ADV spectra

Several statistics were selected to compare mean wave directions obtained near the peak of the spectra for the two measurement techniques. These statistics include mean angular difference (scalar wave direction bias), standard deviation of mean angular difference, root-mean-square error and correlation coefficient. These statistics are defined as follows for X_i (ADV observation) and Y_i (CIIS observation), and a wave direction vector magnitude of unity:

a. Wave Direction Mean Angular Difference, $\langle \Delta\theta \rangle$.

$$\langle \Delta\theta \rangle = \tan^{-1} \left[\frac{\sum \sin(Y_i - X_i)^2}{\sum \cos(Y_i - X_i)^2} \right] \quad (5)$$

b. Standard Deviation of Wave Direction Mean Angular Difference, σ_θ .

$$\varepsilon = \sqrt{1 - \left[(\sin \Delta\theta)^2 + (\cos \Delta\theta)^2 \right]} \quad (6)$$

$$\sigma_\theta = \sin^{-1} \varepsilon \left[1 + 0.1547 \varepsilon^3 \right] \quad (7)$$

c. Wave Direction Root-Mean-Square Error $RMSE_\theta$.

$$RMSE_U = \sqrt{\frac{1}{N} \sum \left\{ [\cos Y_i - \cos X_i - (\langle \cos Y \rangle - \langle \cos X \rangle)]^2 \right\}} \quad (8)$$

$$RMSE_V = \sqrt{\frac{1}{N} \sum \left\{ [\sin Y_i - \sin X_i - (\langle \sin Y \rangle - \langle \sin X \rangle)]^2 \right\}} \quad (9)$$

$$RMSE_\theta = \sqrt{RMSE_U^2 + RMSE_V^2} \quad (10)$$

where subscripts U and V indicate the u-vector and v-vector components.

d. Wave Direction Vector Scatter Index SI_θ .

$$SI_\theta = \frac{RMSE_\theta}{\sqrt{\langle \cos X \rangle^2 + \langle \sin X \rangle^2}} * 100 \quad (11)$$

e. Wave Direction Vector Correlation Coefficient R_θ .

$$R_U = \frac{\sum (\cos X_i - \langle \cos X \rangle)(\cos Y_i - \langle \cos Y \rangle)}{\sqrt{\sum (X_i - \langle \cos X \rangle)^2 \sum (Y_i - \langle \cos Y \rangle)^2}} \quad (12)$$

$$R_V = \frac{\sum (\sin X_i - \langle \sin X \rangle)(\sin Y_i - \langle \sin Y \rangle)}{\sqrt{\sum (X_i - \langle \sin X \rangle)^2 \sum (Y_i - \langle \sin Y \rangle)^2}} \quad (13)$$

$$R_\theta = \sqrt{\frac{1}{2} (R_U^2 + R_V^2)} \quad (14)$$

Figure 37 contains scatterplots of wave directions near the spectral peak for collocated CIIS and ADV observations. Only CIIS observations meeting the coherence cutoff criterion were selected for comparison. Table 6 summarizes the scatterplots. The statistics show good correlation between the two measurement techniques, with low scatter indices. Where the CIIS coherence cutoff criterion is met, wave directions are typically within the reported margin of error for the ADV probe measurements.

Table 6
Structure 1: ADV versus CIIS Validation Statistics for Mean Wave Directions Measured Near the Spectral Peak

Experimental Arrangement	$\langle \Delta\theta \rangle$ deg	σ_θ deg	$RMSE_\theta$ deg	SI_θ	R_θ
Structure 1 ^a	2.64	4.57	4.58	8	0.89
Structure 2	1.98	7.02	6.99	12	0.79
Structure 3 ^b	-5.16	13.08	13.14	24	0.77
Structure 4 ^c	-1.27	7.78	7.66	14	0.93

^a Structure 1: Only experiments X4, X5, X6 analyzed.
^b Structure 3: X1c and X2c did not meet coherence cutoff criterion.
^c Structure 4: X2 did not meet coherence cutoff criterion.

Results

Analysis of pixel array timestacks resulted in estimates of mean spectral density $S(f)$ and vector-mean wave direction $\theta_m(f)$. To demonstrate the video system application, peak vector-mean wave direction for Structure 1, Experiment 2 (random wave, $f_{peak} = 1.25$ Hz) is indicated by arrows (scaled by wave celerity) superimposed on a rectified snapshot of the wave field in Figure 38. Arrows with a circled tail represent directions obtained from analyses meeting the strict coherence cutoff criterion. Some arrows without circled tails are spurious in direction and magnitude in the diffraction area behind the breakwater.

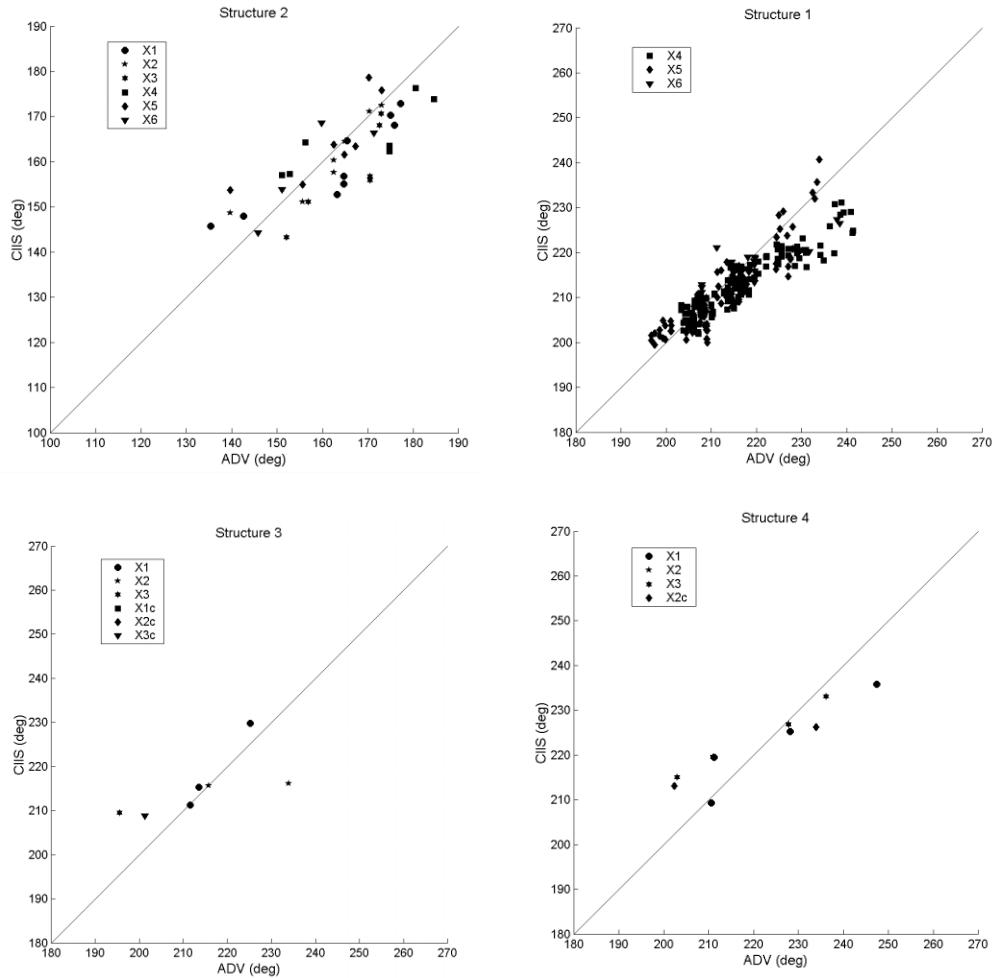

Figure 37. CIIS and ADV intercomparison for wave direction measurements obtained near the spectral peak for Structures 1 through 4. Solid line is 1:1 slope. Only CIIS observations meeting the coherence cutoff criterion were selected for analysis

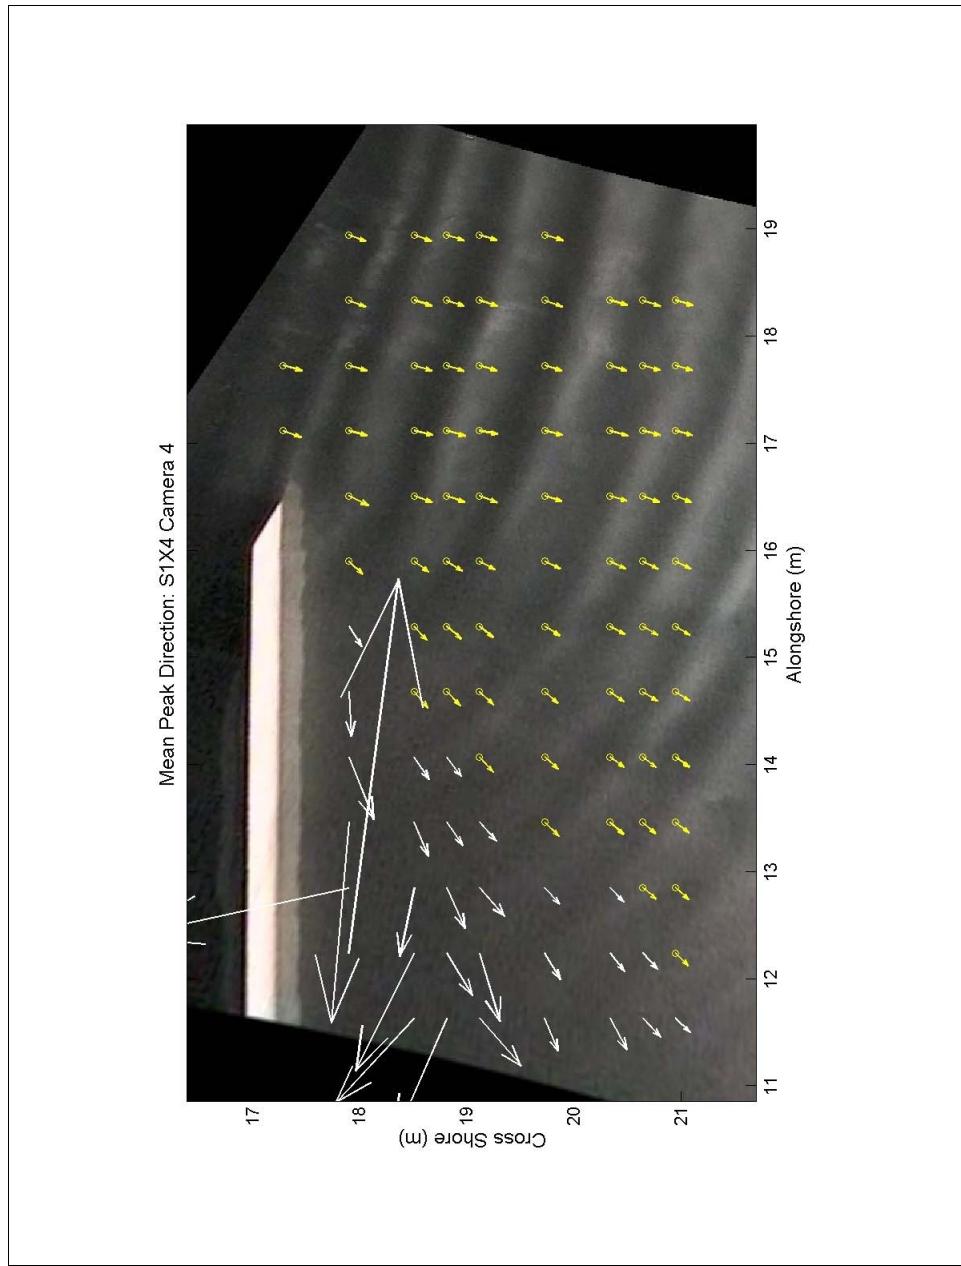

Figure 38. Peak vector-mean wave direction CIIS analysis for Structure 1, Experiment 4, Camera 4

Several general sources of measurement error are identified and the accuracy of the CIIS may be improved upon in future experimentation. In the wave diffraction region where wave height is significantly reduced or in regions of the measurement area that are poorly illuminated, the visual signal of the wave degrades due to lack of contrast. Figure 38 exemplifies lack of image contrast in the diffraction region behind the breakwater structure where the wave direction arrows are spurious. Image contrast may be improved by adjustment of the lens iris, improved directional illumination, and use of a monochromatic camera system. With a monochromatic camera, signal degradation may be reduced and image contrast improved. In the Structure 3 and 4 experiments, the camera and sources of illumination were directed along the axis of the inlet. The rear face of waves was illuminated as they propagated through the inlet to the bay. Waves entering the bay were refracted and diffracted, with the sharpest turning angles at the shoulder of the inlet. In this area, wave crests approached an alignment parallel with spectral illumination, reducing the variance in radiance between the forward and rear faces of the wave received by the camera. Put simply, the ability to visually distinguish between front and rear faces of the wave was diminished.

Figure 39 shows the effect of undesired light reflection on the video analysis. In the upper right corner of the image the reflection of the jetty structure is observed on the water surface. The shape of the reflection deforms with perturbations of the water surface, and the channels of the pixel array record its visual signal. The contaminated time-history records prevent the phase relationship between array channels to be determined accurately for the phenomenon of interest. Shadows cast within a measurement array may also cause this contamination of signal.

Another potential source of measurement error is array geometry. It is assumed that processes being measured are homogeneous within the array aperture. However, this may not be the case where large changes in direction are occurring over a small area. Measurement array geometry may be optimized to better resolve wave direction where waves are making large turning angles approaching a direction perpendicular to the long axis of the array. Waves breaking on currents and the shore also produced inhomogeneities within the measurement array.

For each model configuration, experiment, and camera view, spectral peak vector-mean wave direction plots are presented in Appendix Q. Due to the large volume of analysis results generated by this investigation, $S(f)$ and $\theta_m(f)$ are presented in tabular form in ASCII data files compiled on a CD that accompanies this report. It describes the naming convention and file formats for the data contained on the CD.

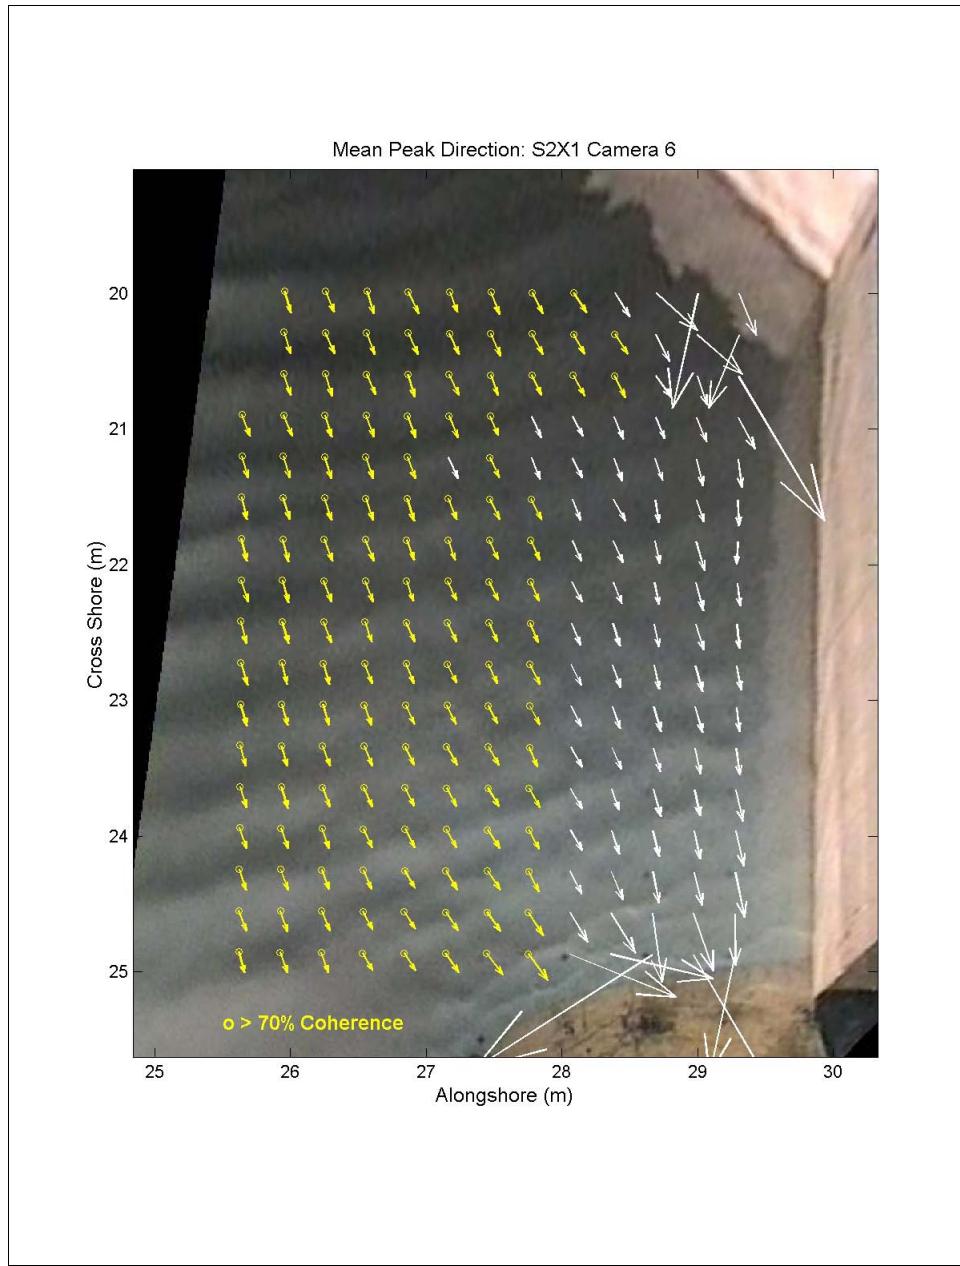

Figure 39. Peak vector-mean wave direction CIIS analysis for Structure 2, Experiment 1, Camera 6

6 Summary and Conclusions

Summary

Water level (wave height variation) and wave directional data were collected at numerous locations for situations typical of coastal inlets. The objective was to supply data sets that contain information with diffracting, refracting, and shoaling waves to aid in the development of numerical models that simulate field conditions. The measurements were collected at an idealized inlet with smooth contours. The following configurations were examined:

- a. An offshore breakwater directly up-coast of the inlet region with a bathymetry behind it that has a sloping bottom terminating at the beach (Structure 1).
- b. A dogleg jetty on one side of a coastal inlet (Structure 2).
- c. An unjettied inlet, with measurements collected on the bay side (Structure 3). These experiments were performed with and without a flood current.
- d. A jettied inlet, with measurements collected on the bay side (Structure 4). These experiments were performed with and without a flood current.

Results from a physical model laboratory study of spatially dense wave direction measurements in the diffraction regions of coastal inlet structures were presented. To obtain these measurements, a video-based metric system was developed, implemented, and validated. This system is called the Coastal Inlets Imaging System (CIIS). Although the system was developed using commercially available hardware and standard image processing and photogrammetric techniques, the application of the CIIS to provide spatially dense measures of wave direction over a large area of interest represents an advance in wave measurement technology. Experimentation confirms that the system provides spatially dense and accurate measures of wave direction over a large area of interest, which is not economically obtained by standard in situ methods.

Conclusions

Based on the information presented in this report, it is concluded that:

- a. The comprehensive data presented in this report will provide calibration information for numerical models of wave refraction and diffraction.

- b.* The CIIS was successfully validated and provided wave-direction—frequency information in the difficult physical model environment.

Appendix A

Notation

2-D	Two-dimensional
3-D	Three-dimensional
ADV	Acoustic Doppler Velocimeter
C	Wave celerity
C1, C2, C3, C4, C5, C6	Cameras 1, 2, 3, 4, 5, 6
CD	Compact disc
CIIS	Coastal Inlets Imaging System
CIRP	Coastal Inlets Research Program
<i>d</i>	Still-water depth, ft
<i>e</i>	Average water level relative to pretest still-water level, ft, referenced to mean water level
<i>f</i>	Frequency, 1 sec
f	Lens focal length
GCP	Ground control point
H_a	Average wave height from down-crossing time series analysis
H_m	Maximum wave height, ft
H_s	Significant wave height from down-crossing time series analysis, ft
<i>i</i>	$\sqrt{-1}$
<i>I</i>	Pixel intensity
<i>k</i>	Wave number
k_x	Cross-shore wave number component
k_y	Alongshore wave number component
k_{rms}	Root-mean-square average wave number

ℓ	Length
N	Number of array elements
NA	Not applicable
P_{pp}	Autospectra of pixel sensor pair at $[x_p, y_p]$
P_{qq}	Autospectra of pixel sensor pair at $[x_q, y_q]$
PUV	Pressure and horizontal velocity components
Q_{pq}	Quad-spectrum of pixel sensor pair location in 3-D coordinate system $[x_p, y_p]$ and $[x_q, y_q]$
R_U	u-vector component of wave direction correlation coefficient
R_V	v-vector component of wave direction correlation coefficient
R_θ	Wave direction vector correlation coefficient
$RMSE_U$	u-vector component of wave direction root-mean-square error
$RMSE_V$	v-vector component of wave direction root-mean-square error
$RMSE_\theta$	Wave direction root-mean-square error
$S(f)$	Mean spectral density as a function of frequency presented in units of m^2/Hz for ADV and I^2/Hz for CIIS
$S(f)_n$	Normalized mean spectral density as a function of frequency presented in units of m^2/Hz for ADV and I^2/Hz for CIIS. Normalized by maximum $S(f)$
SI_θ	Wave direction vector scatter index
t	Time
T_p	Peak wave period
T_s	Significant wave period, sec
u	Horizontal image coordinate
v	Vertical image coordinate
VITC	Vertical Interval Time Code
x	Distance offshore; X-coordinate of imaged object in 3-D coordinate system
x_c	X-coordinate of camera location in 3-D coordinate system
$(x_p, y_p), (x_q, y_q)$	Pixel sensor pair locations in 3-D coordinate system

X	X-axis, real-world 3-D coordinate system (cross-shore)
X_i	ADV observation for statistical analysis
y	Y-coordinate of imaged object in 3-D coordinate system
y_c	Y-coordinate of camera location in 3-D coordinate system
Y	Y-axis, real-world 3-D coordinate system (alongshore)
Y_i	CIIS observation for statistical analysis
z	Z-coordinate of imaged object in 3-D coordinate system
z_c	Z-coordinate of camera location in 3-D coordinate system
Z	Z-axis, real-world 3-D coordinate system
α	Phillips constant
α_{pq}	Wave number coefficient
γ	Enhancement factor
η	Water-surface elevation
θ_m	Vector-mean wave direction
$\theta_m(f)$	Vector-mean wave direction as function of frequency presented in units of deg relative to model coordinate system
$\theta_m(f)_c$	Vector-mean wave direction as a function of frequency presented in units of deg relative to model coordinate system following application of coherence cutoff criteria
$\langle \Delta\theta \rangle$	Wave direction mean angular difference
σ	Camera roll rotation angle
σ_α	Low-frequency peak decay factor
σ_b	High-frequency peak decay factor
σ_θ	Standard deviation of wave direction mean angular difference
τ	Camera tilt rotation angle
ϕ	Camera pan rotation angle

Appendix B

Data Tables for Structure 1

Tables B1 through B30 list measurements for the waves experiments in Structure 1. The tables include the still-water depth d , average water surface elevation e , significant wave period T_s , significant wave height H_s , average wave height H_a , and maximum wave height H_m . The gauge locations are shown in Figure 5, and Figure B1 provides an enlargement with concentration on placements of the Acoustic Doppler Velocimeter (ADV) probes. Gauges 1, 2, 3, 4, and 5 are the furthest offshore (near the generator). Gauges 6, 7, 8, 9, and 10 are also offshore, but nearer to breakwater. The gauge spacing for the rack gauges 11-20 and 21-30 is 0.6 m (2 ft) between consecutive gauges. The gauge locations in the basin coordinate system are given in Appendix L. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix C

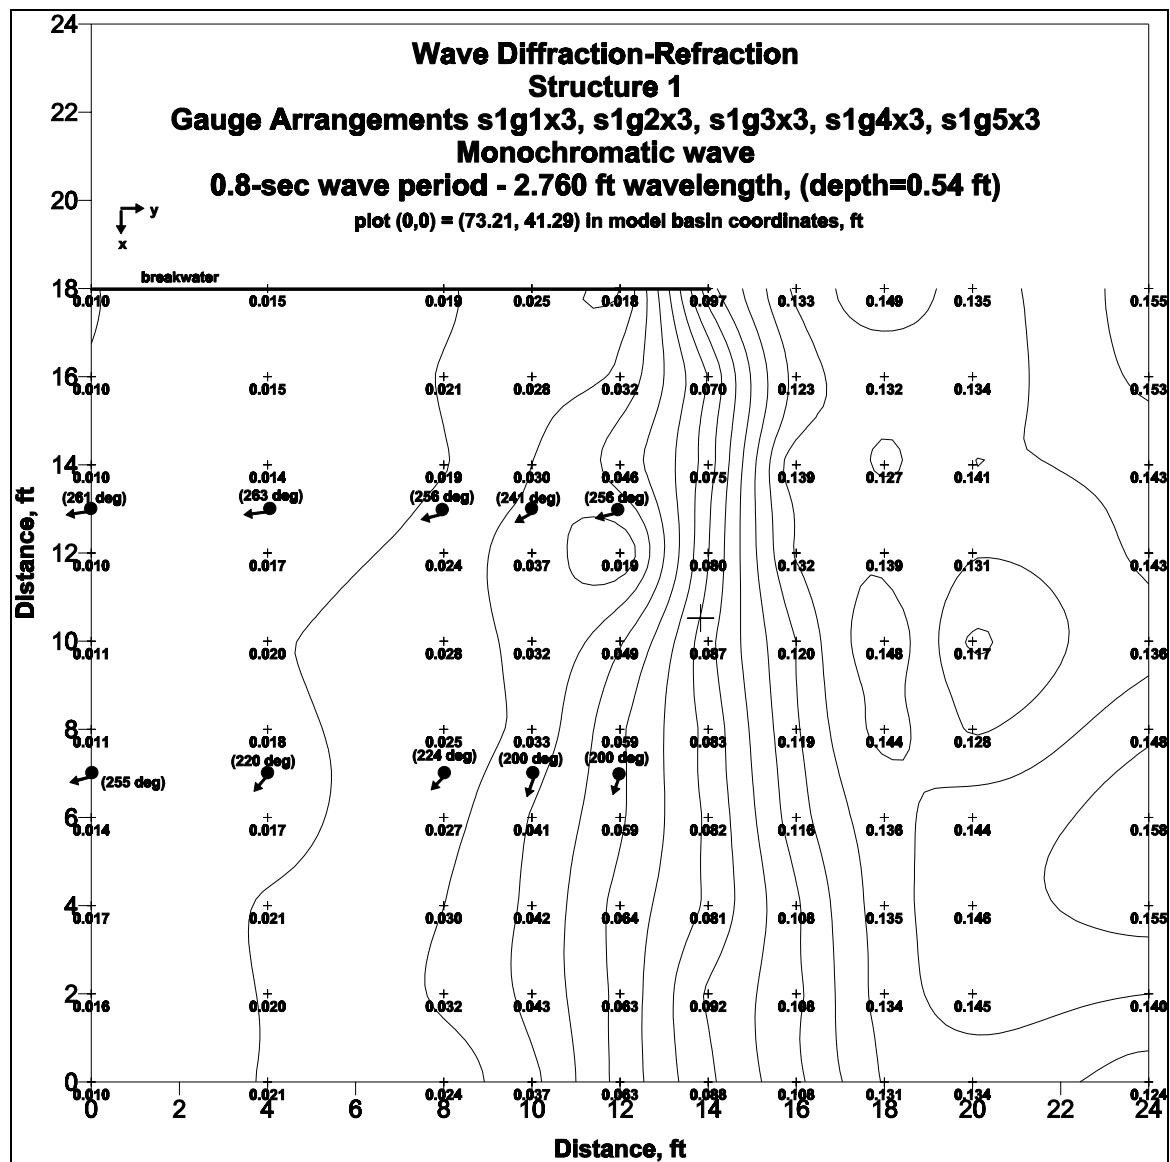

Wave Diffraction-Refraction

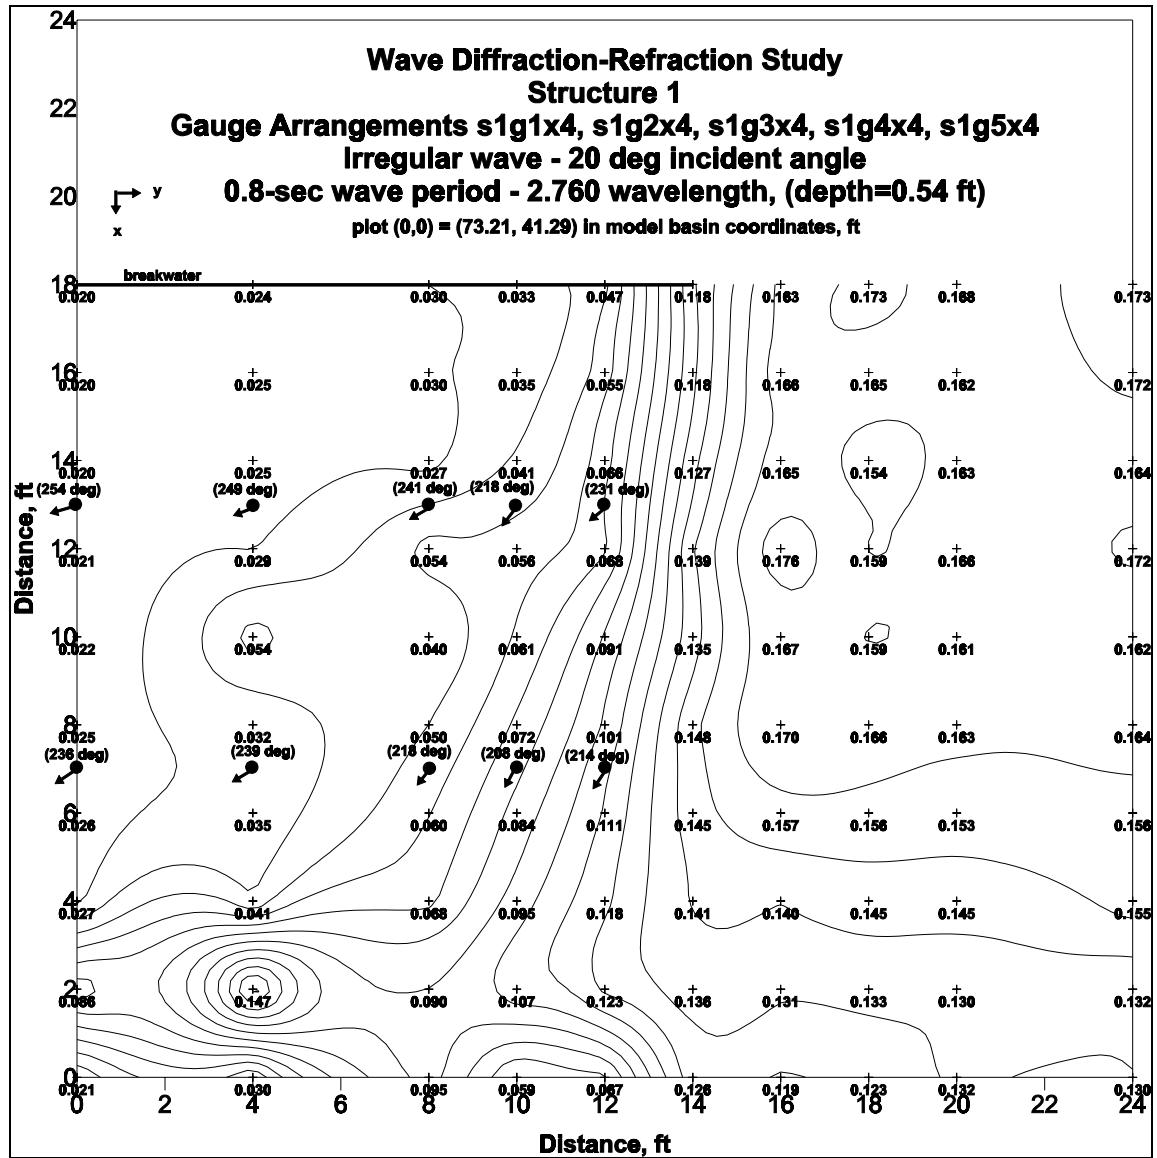

Plots for Structure 1

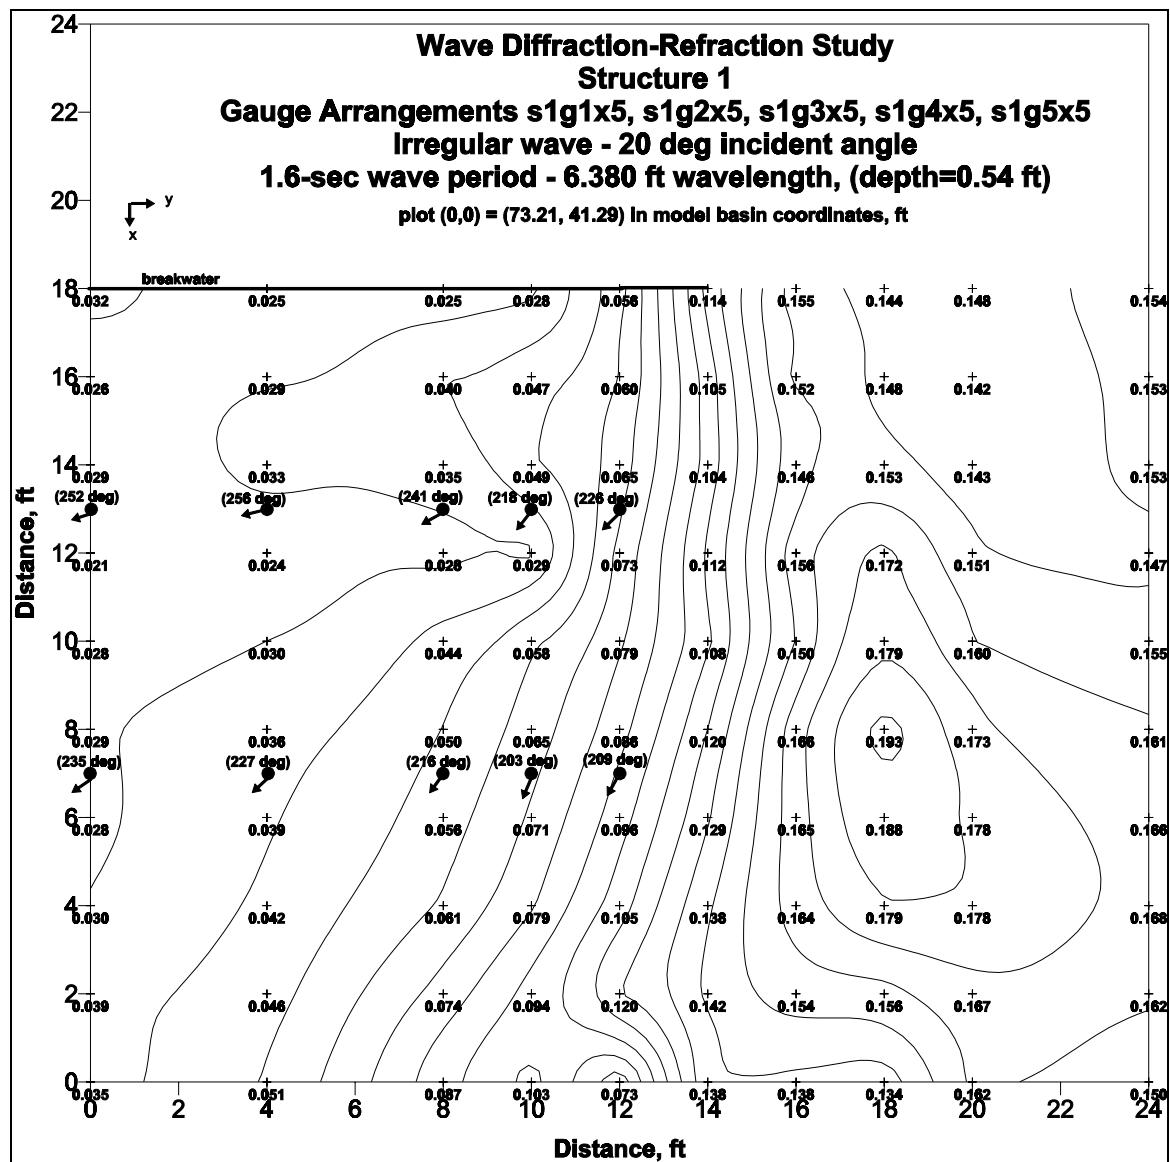

The wave diffraction-refraction plots in this appendix are contour maps describing the wave height transformation at the five different gauge arrangements. Contour interval is 0.003 m (0.01 ft). The vectors on the maps depict the peak wave direction acquired at the peak period from the Acoustic Doppler Velocimeter (ADV) probe. Table C1 summarizes ADV probe vector plot data for Structure 1. To convert measurements given in feet to meters, multiply by 0.3048. To convert measurements given in square feet to square meters, multiply by 0.093.

Appendix D

Data Tables for Structure 2

Tables D1 through D30 list measurements for the wave experiments in Structure 2. The tables include the still-water depth d , average water surface elevation e , significant wave period T_s , significant wave height H_s , average wave height H_a , and maximum wave height H_m . The gauge locations are shown in Figure 8, and Figure D1 provides an enlargement with concentration on placement of the Acoustic Doppler Velocimeter (ADV) probes. Gauges 1, 2, 3, 4, and 5 are the furthest offshore (near the generator). Gauges 6, 7, 8, 9, and 10 are also offshore, but nearer to the jetty. The gauge spacing for the rack gauges, 11-20 and 21-30, is 0.6 m (2 ft) between consecutive gauges. The gauge locations in the basin coordinate system are given in Appendix M. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix E

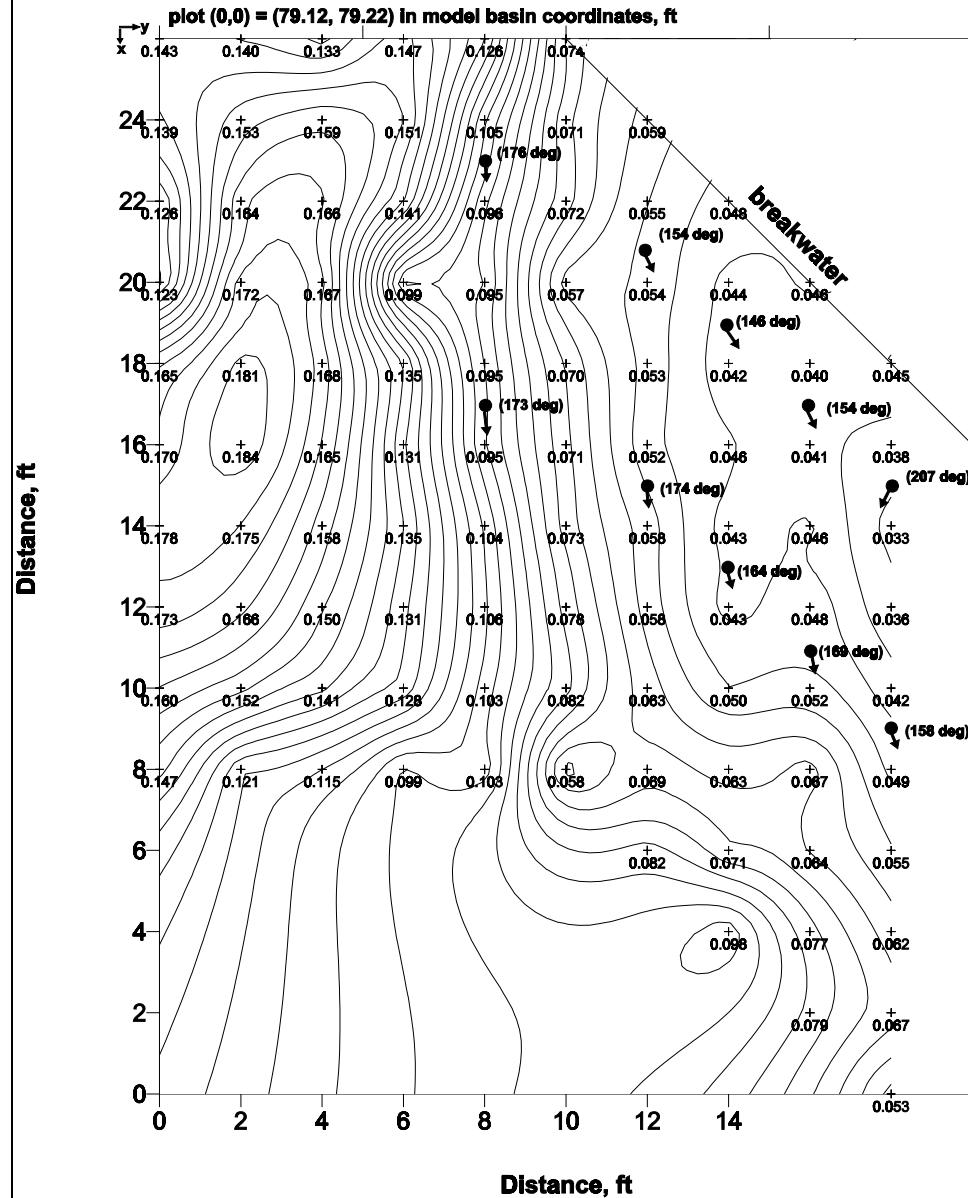

Wave Diffraction-Refraction

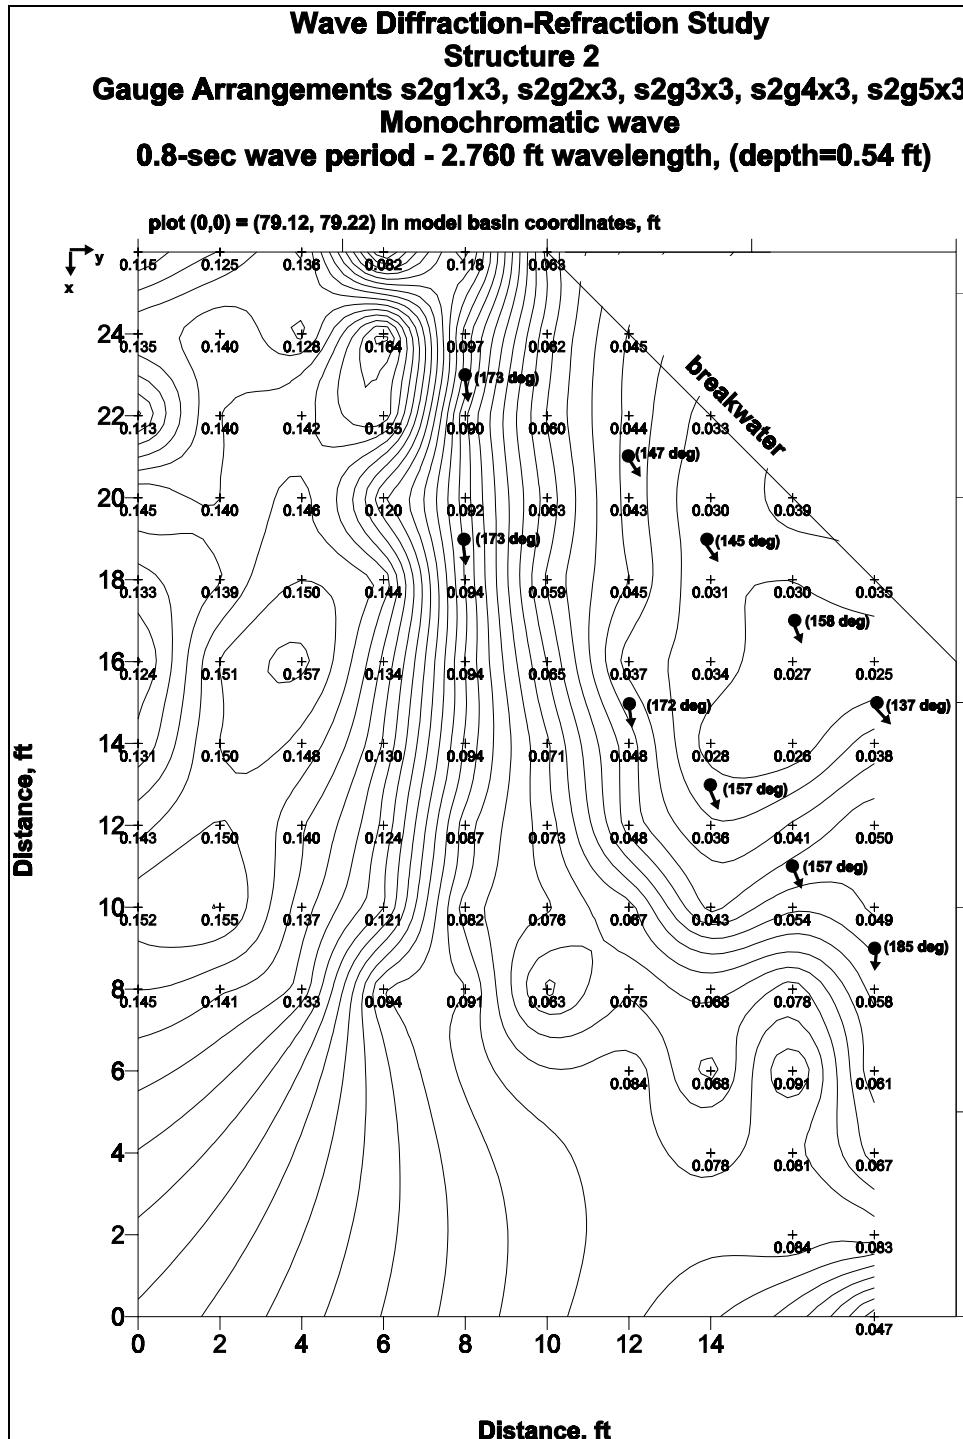

Plots for Structure 2

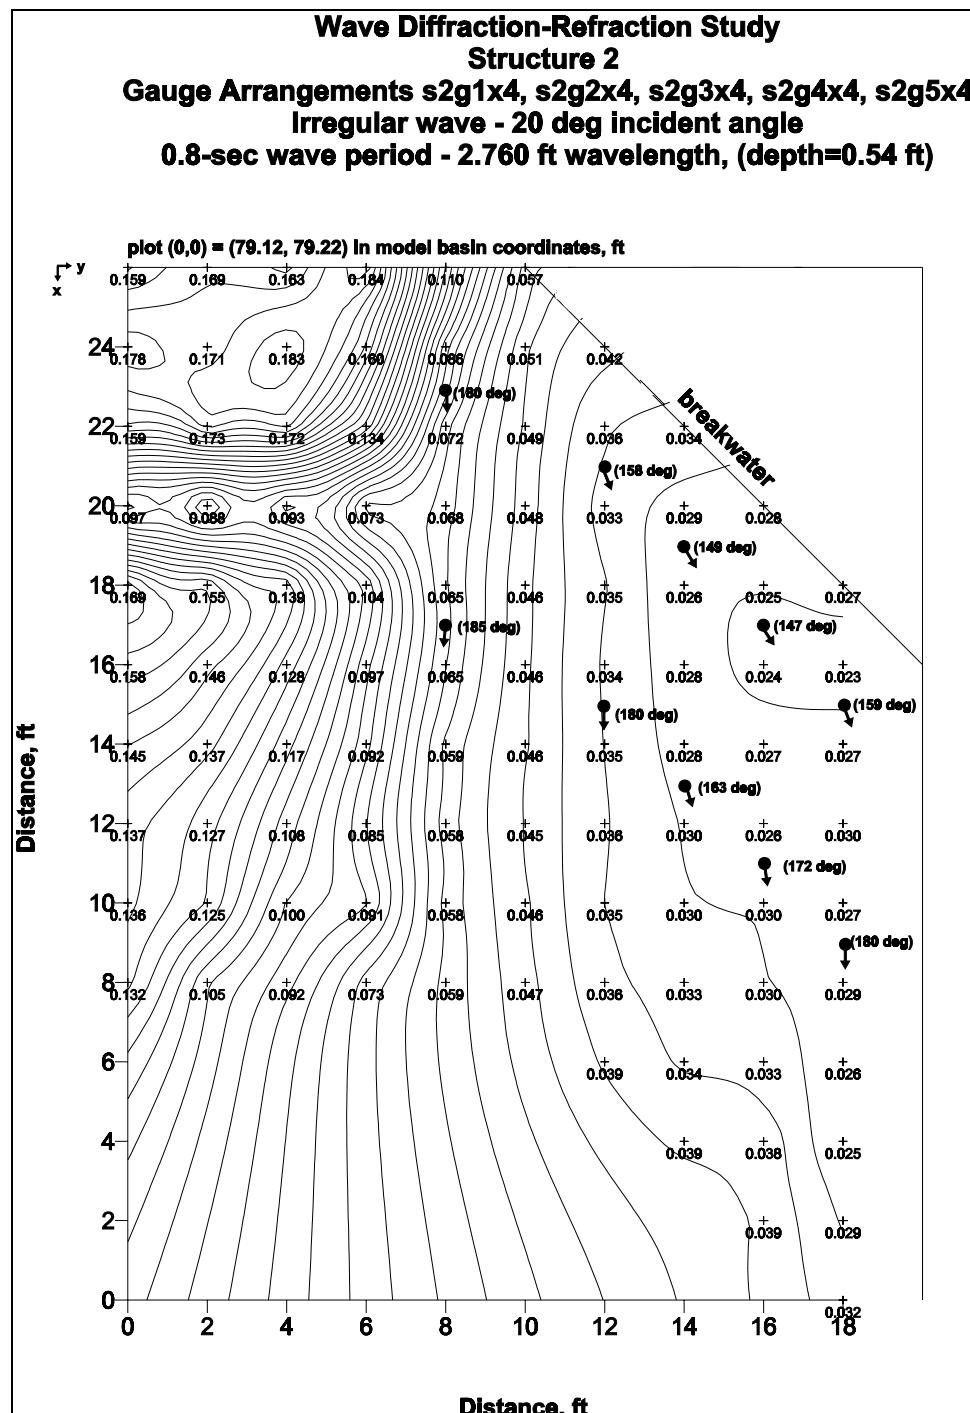

The wave diffraction-refraction plots in this appendix are contour maps describing the inlet wave height transformation at the five different gauge arrangements. Contour interval is 0.003 m (0.01 ft). The vectors on the maps depict the peak wave direction acquired at the peak period from the Acoustic Doppler Velocimeter (ADV) probe. Table E1 summarizes ADV probe vector plot data for Structure 2. To convert measurements given in feet to meters, multiply by 0.3048. To convert measurements given in square feet to square meters, multiply by 0.093.

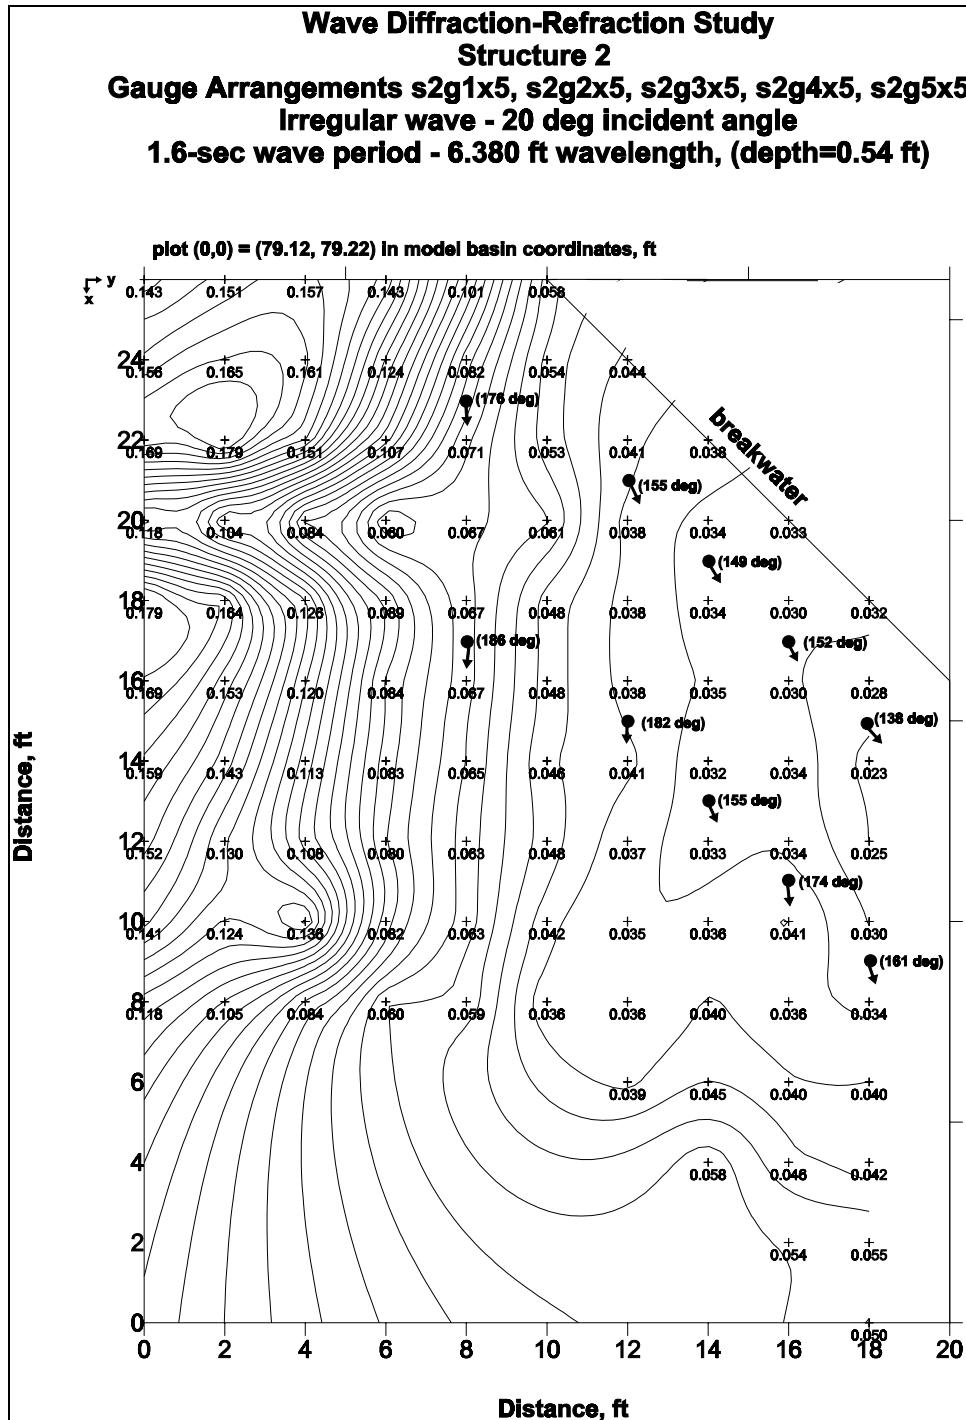

Wave Diffraction-Refraction Study

Appendix F

Data Tables for Structure 3

Tables F1 through F24 list measurements for the wave experiments in Structure 3. The tables include the still-water depth d , average water surface elevation e , significant wave period T_s , significant wave height H_s , average wave height H_a , and maximum wave height H_m . The gauge locations are shown in Figure 9, and Figure F1 provides an enlargement with concentration on placement of the Acoustic Doppler Velocimeter (ADV) probes. Gauges 1, 2, 3, and 4 are the furthest offshore (near the generator). Gauges 8, 9, and 10 are in the inlet throat, and Gauges 6 and 7 are in the entrance channel. The gauge spacing for the rack gauges 11-20 and 21-30 is 0.6 m (2 ft) between consecutive gauges. The gauge locations in the basin coordinate system are given in Appendix N. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix G

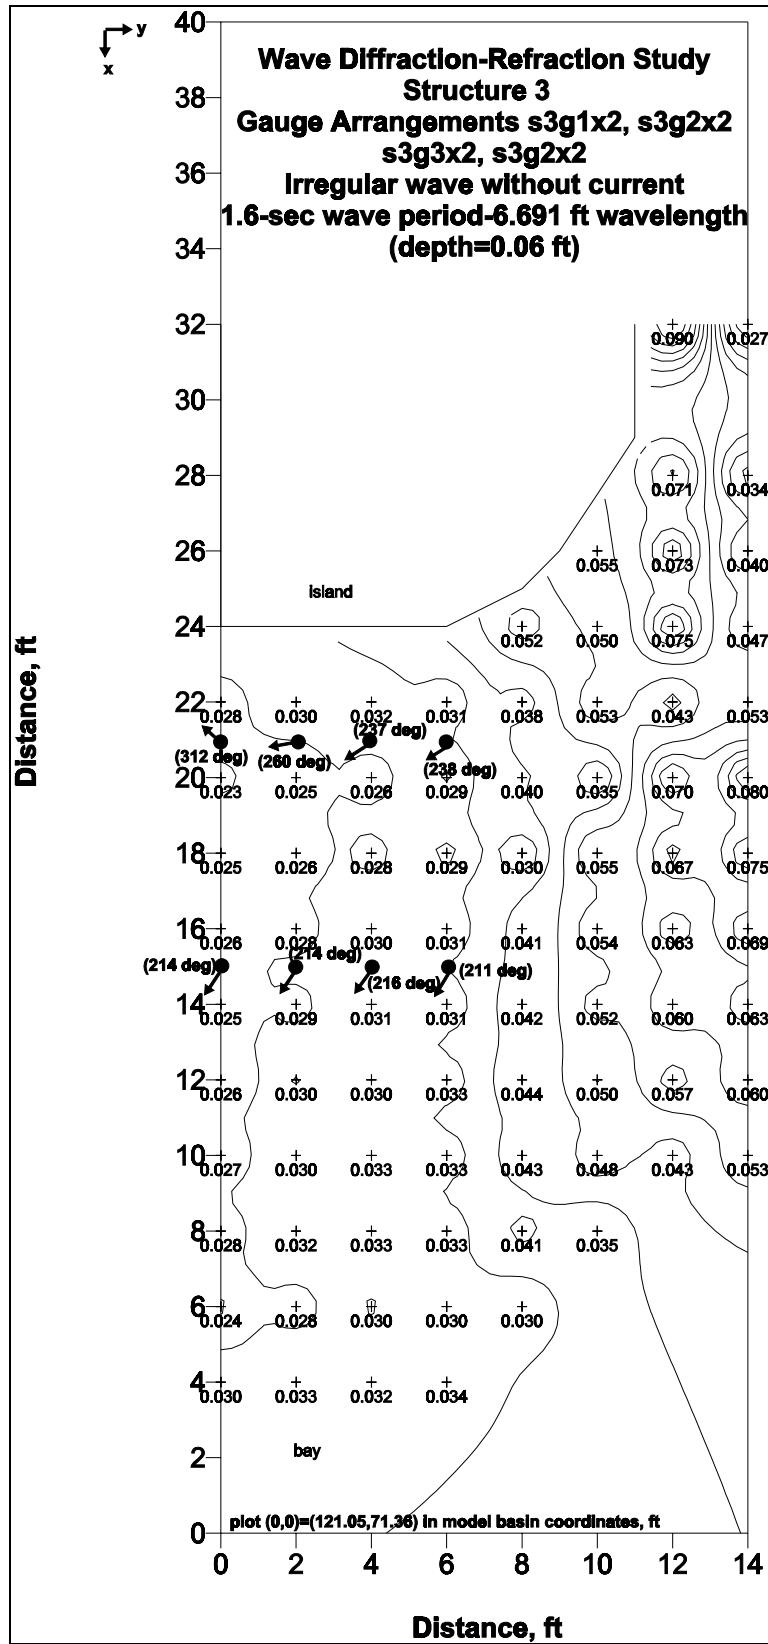

Wave Diffraction-Refraction

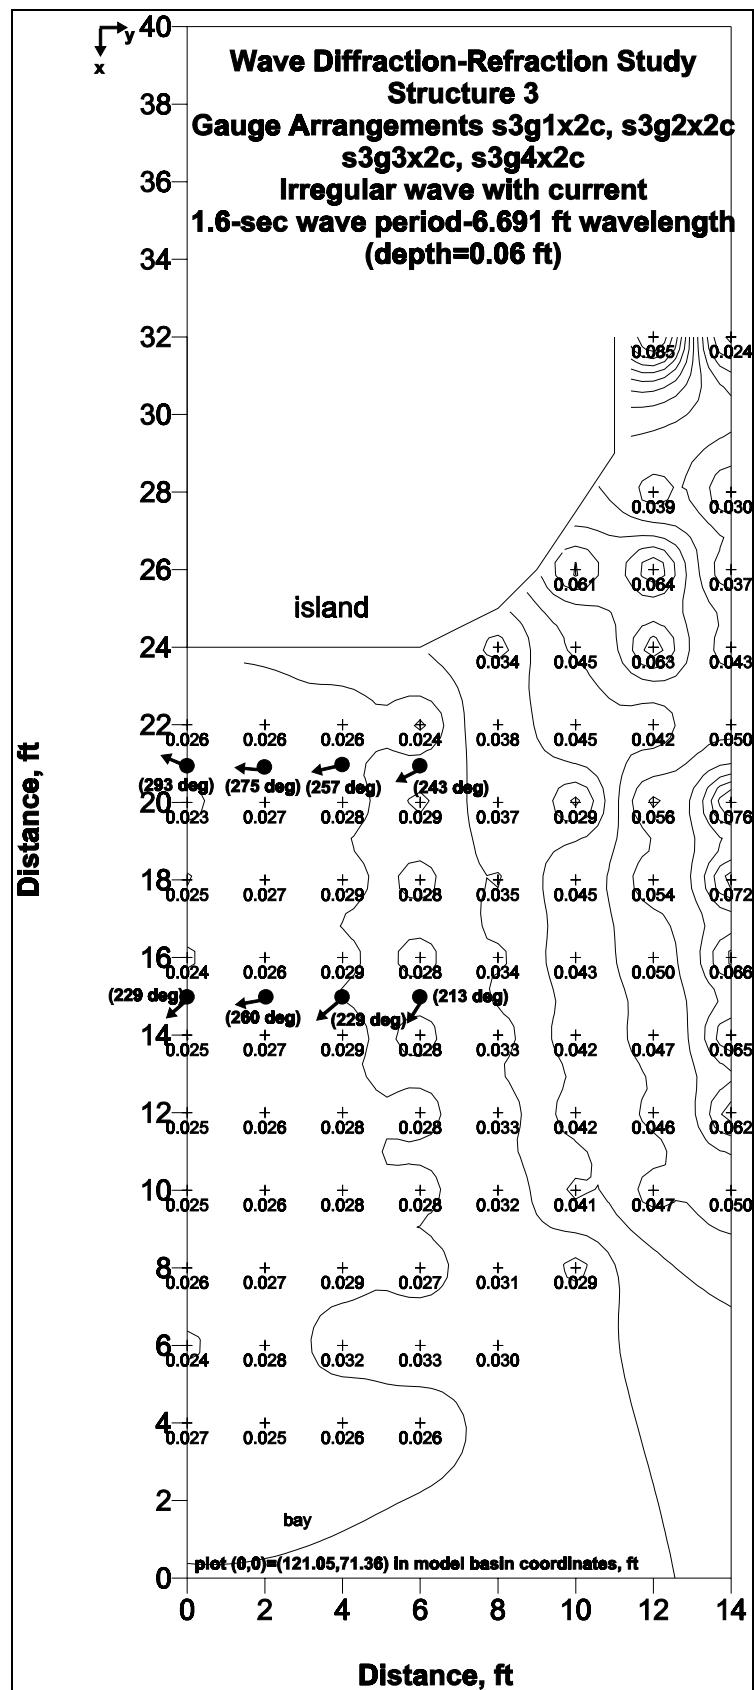

Plots for Structure 3

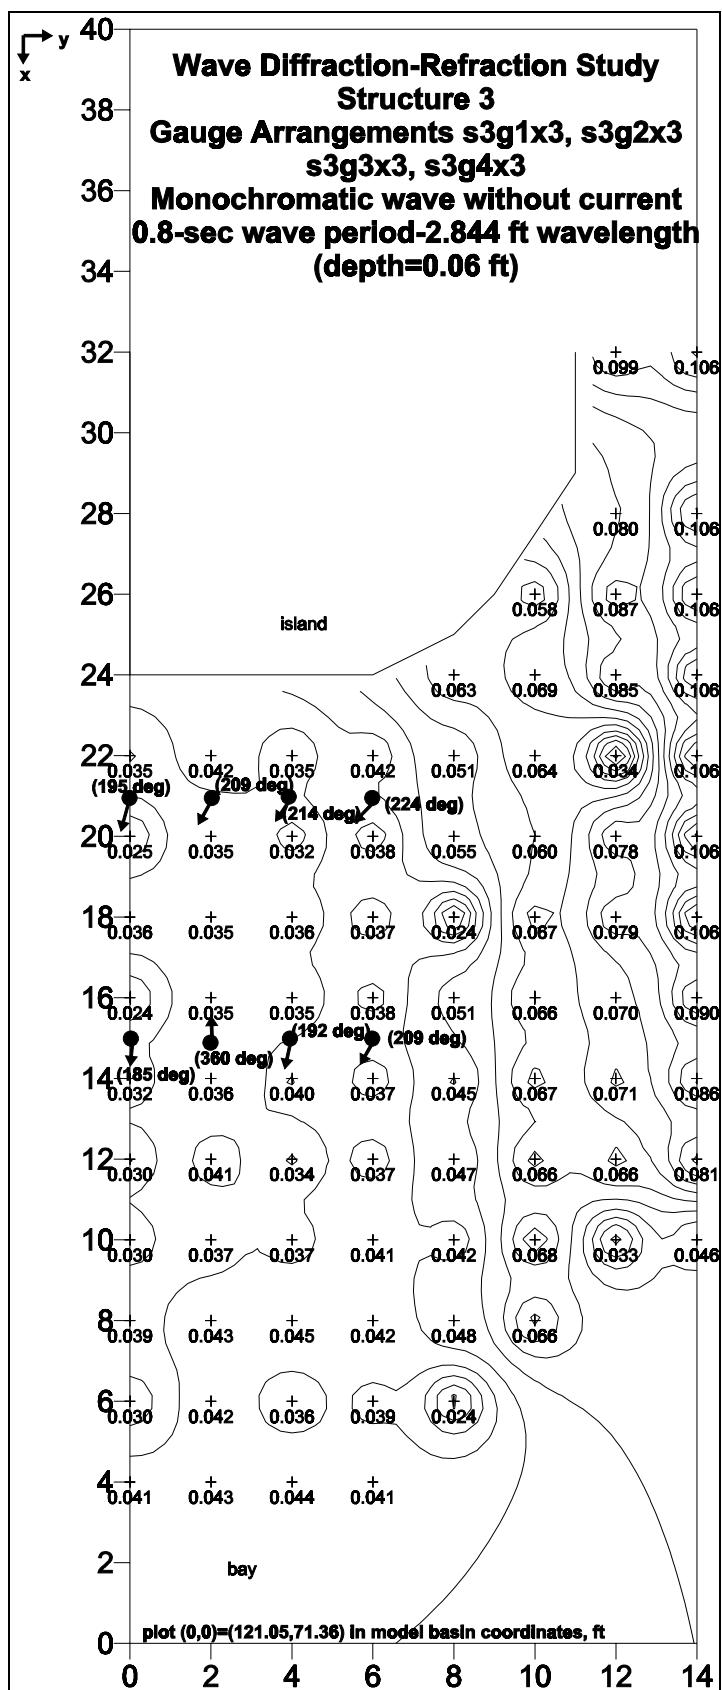

The wave diffraction-refraction plots in this appendix are contour maps describing wave height transformation at the four different gauge arrangements. Contour interval is 0.003 m (0.01 ft). The vectors on the maps depict the peak wave direction acquired at the peak period from the Acoustic Doppler Velocimeter (ADV) probe. Table G1 presents ADV probe vector plot data for Structure 3. To convert measurements given in feet to meters, multiply by 0.3048. To convert measurements given in square feet to square meters, multiply by 0.093.

Appendix H

Data Tables for Structure 4

Tables H1 through H16 list measurements for the wave experiments in Structure 4. The tables include the still-water depth d , average water surface elevation e , significant wave period T_s , significant wave height H_s , average wave height H_a , and maximum wave height H_m . The gauge locations are shown in Figure 10, and Figure H1 provides an enlargement with concentration on placement of the Acoustic Doppler Velocimeter (ADV) probes. Gauges 1, 2, 3, and 4 are the furthest offshore (near the generator). Gauges 8, 9, and 10 are in the inlet throat, and Gauges 6 and 7 are in the entrance channel. The gauge spacing for the rack gauges 11-20 and 21-30 is 0.6 m (2 ft) between consecutive gauges. The gauge locations in the basin coordinate system are given in Appendix O. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix I

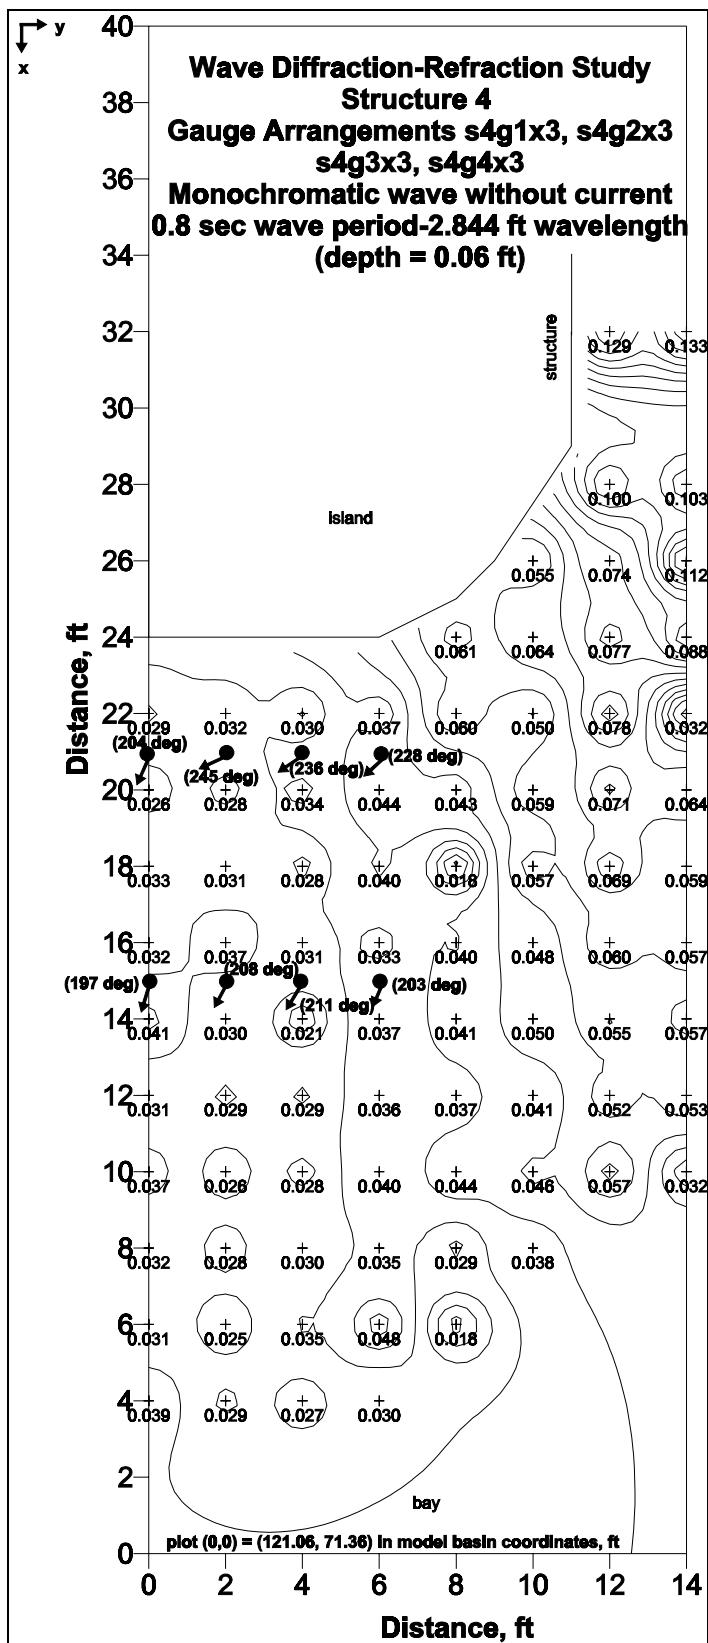

Wave Diffraction-Refraction

Plots for Structure 4

The wave diffraction-refraction plots in this appendix are contour maps describing wave height transformation at the four different gauge arrangements. Contour interval is 0.003 m (0.01 ft). The vectors on the maps depict the peak wave direction acquired at the peak period from the Acoustic Doppler Velocimeter (ADV) probe. Table I1 presents Structure 4 ADV probe vector plot data. To convert measurements given in feet to meters, multiply by 0.3048. To convert measurements given in square feet to square meters, multiply by 0.093.

Appendix J

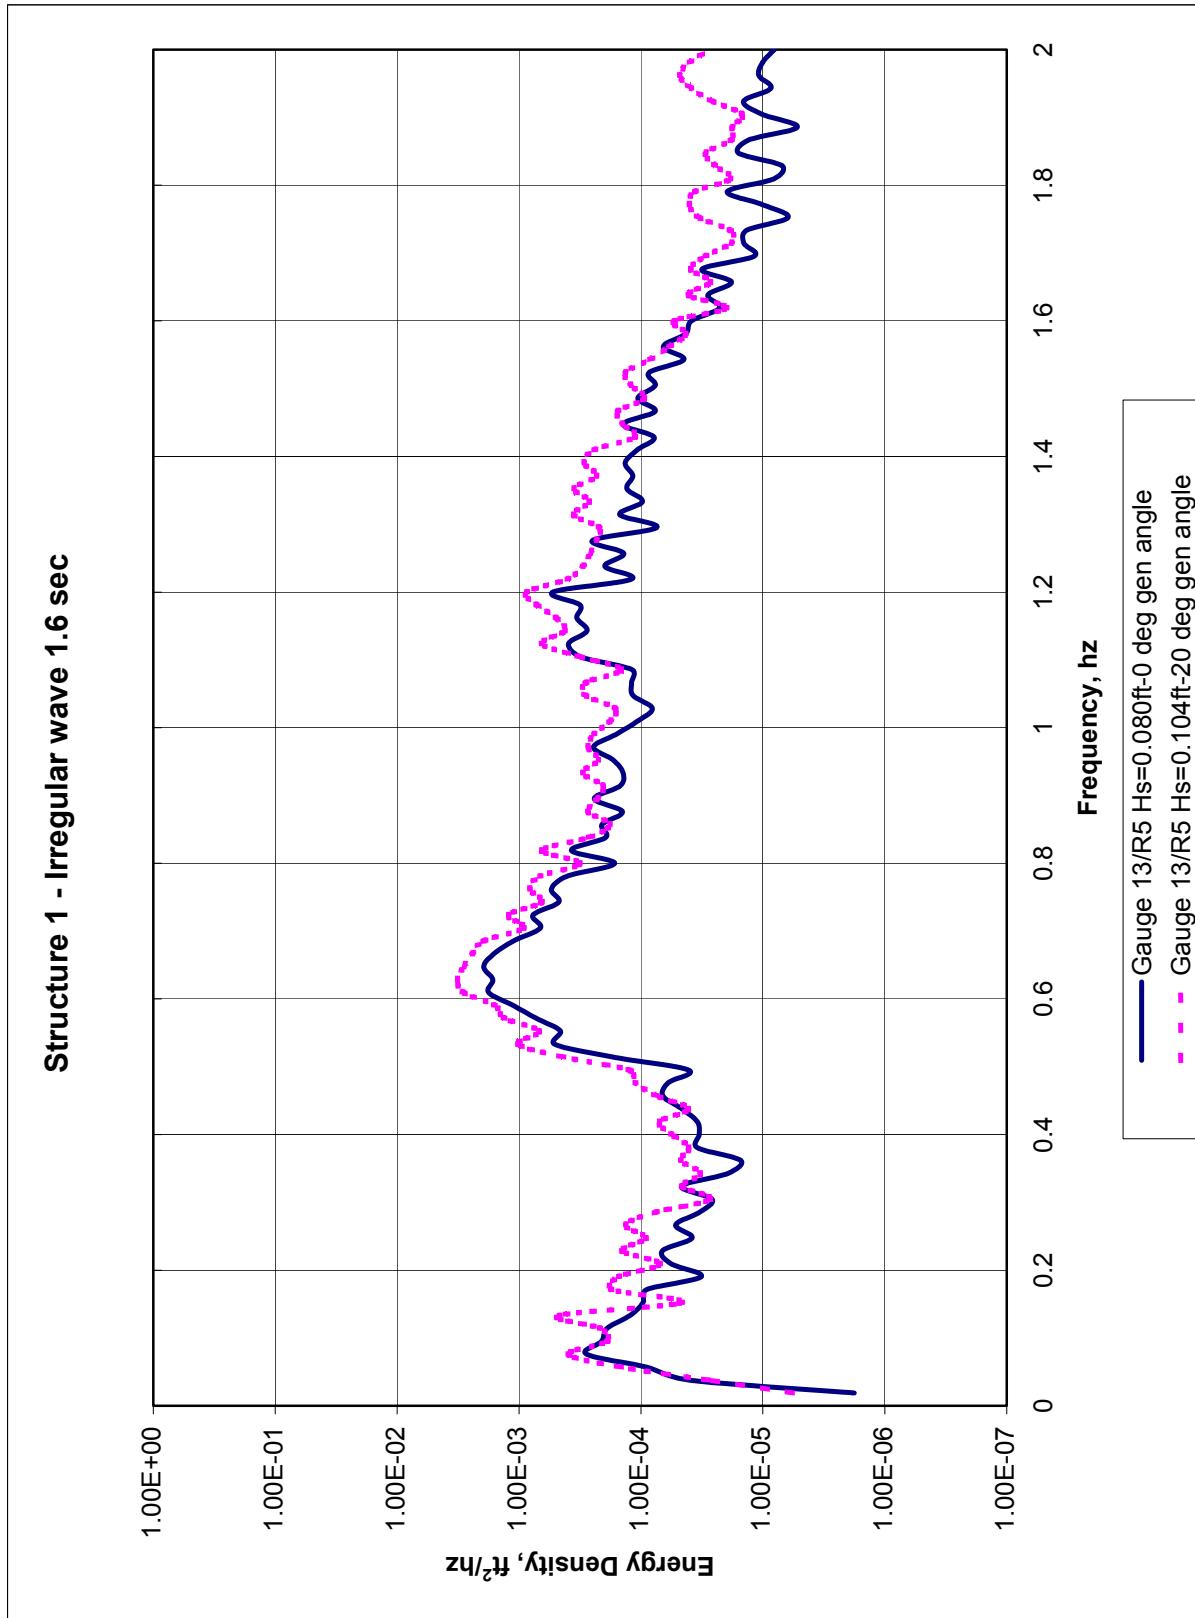

Energy Density Versus Frequency Plots

Representative wave gauges were chosen for creation of spectral energy density versus frequency plots. Locations of gauges for Structure 1 are shown in Figures 5 and B1, for Structure 2 Figures 8 and D1, for Structure 3 Figures 9 and F1, and for Structure 4, Figures 10 and H1. To convert measurements given in feet to meters, multiply by 0.3048. To convert measurements given in square feet to square meters, multiply by 0.093.

Structure 2 - Irregular wave 0.8 sec, 0 deg

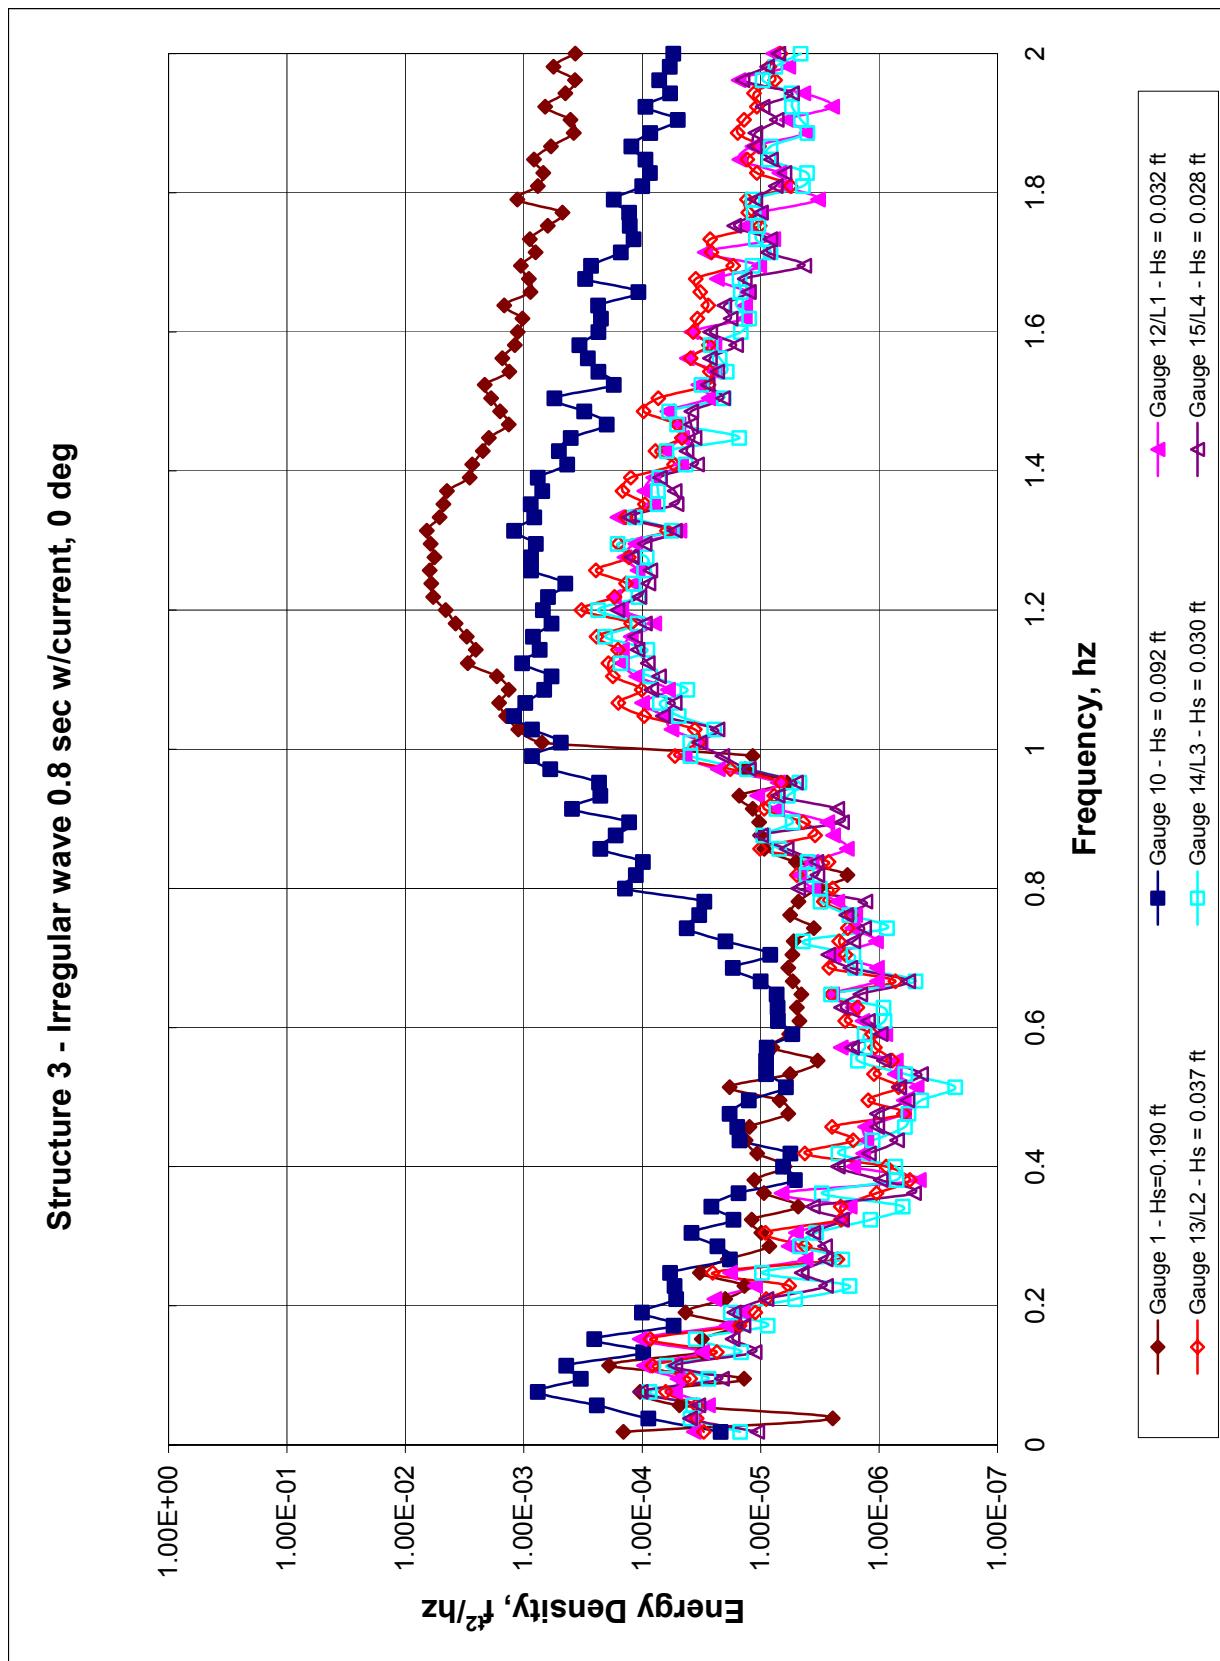

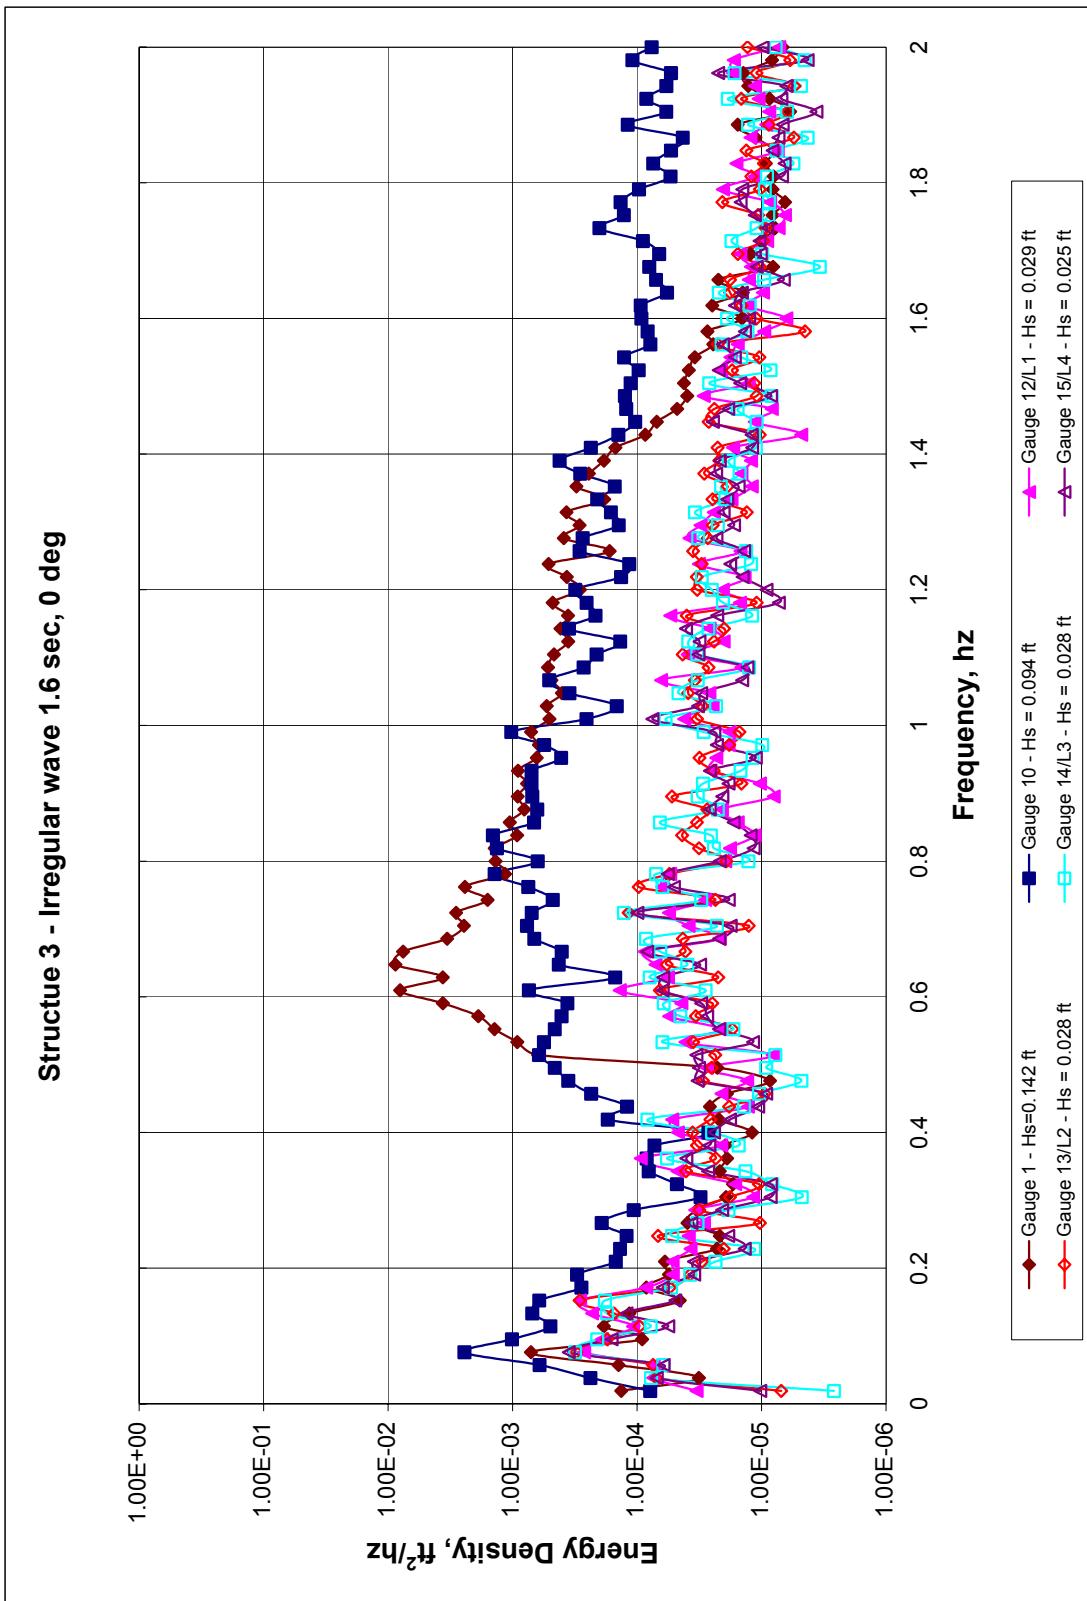

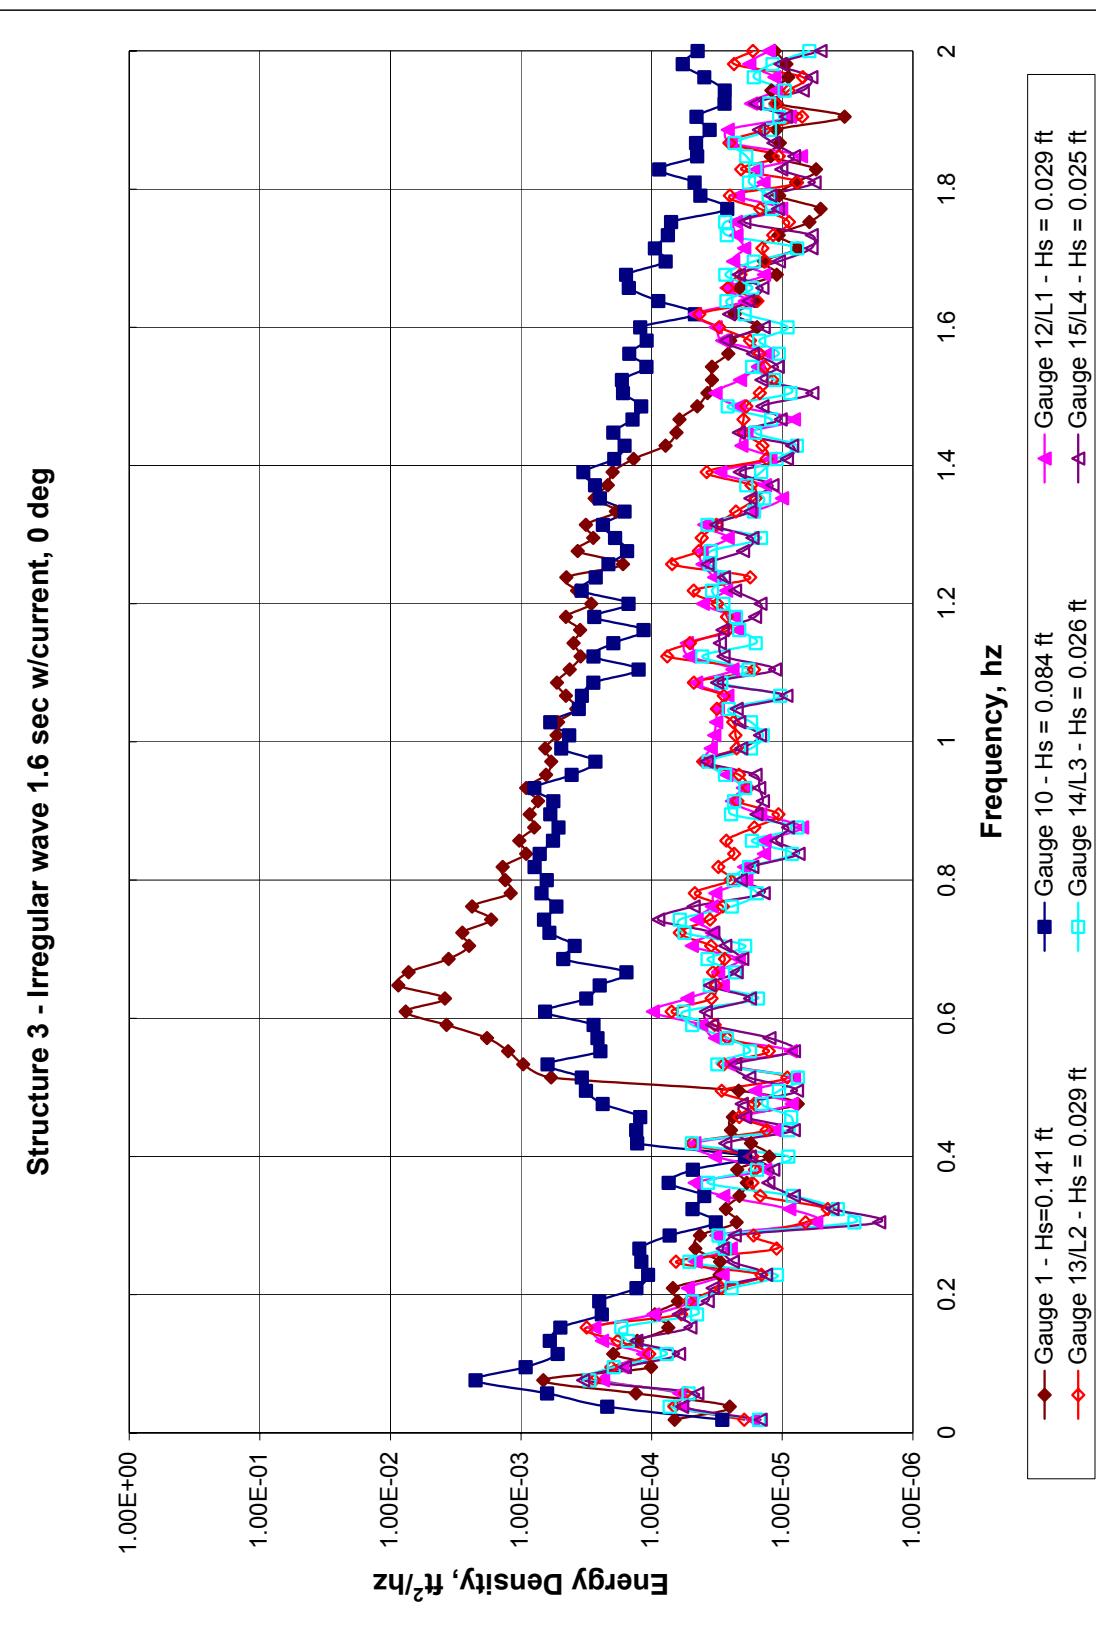

Structure 2 - Monochromatic wave 0.8 sec, 0 deg

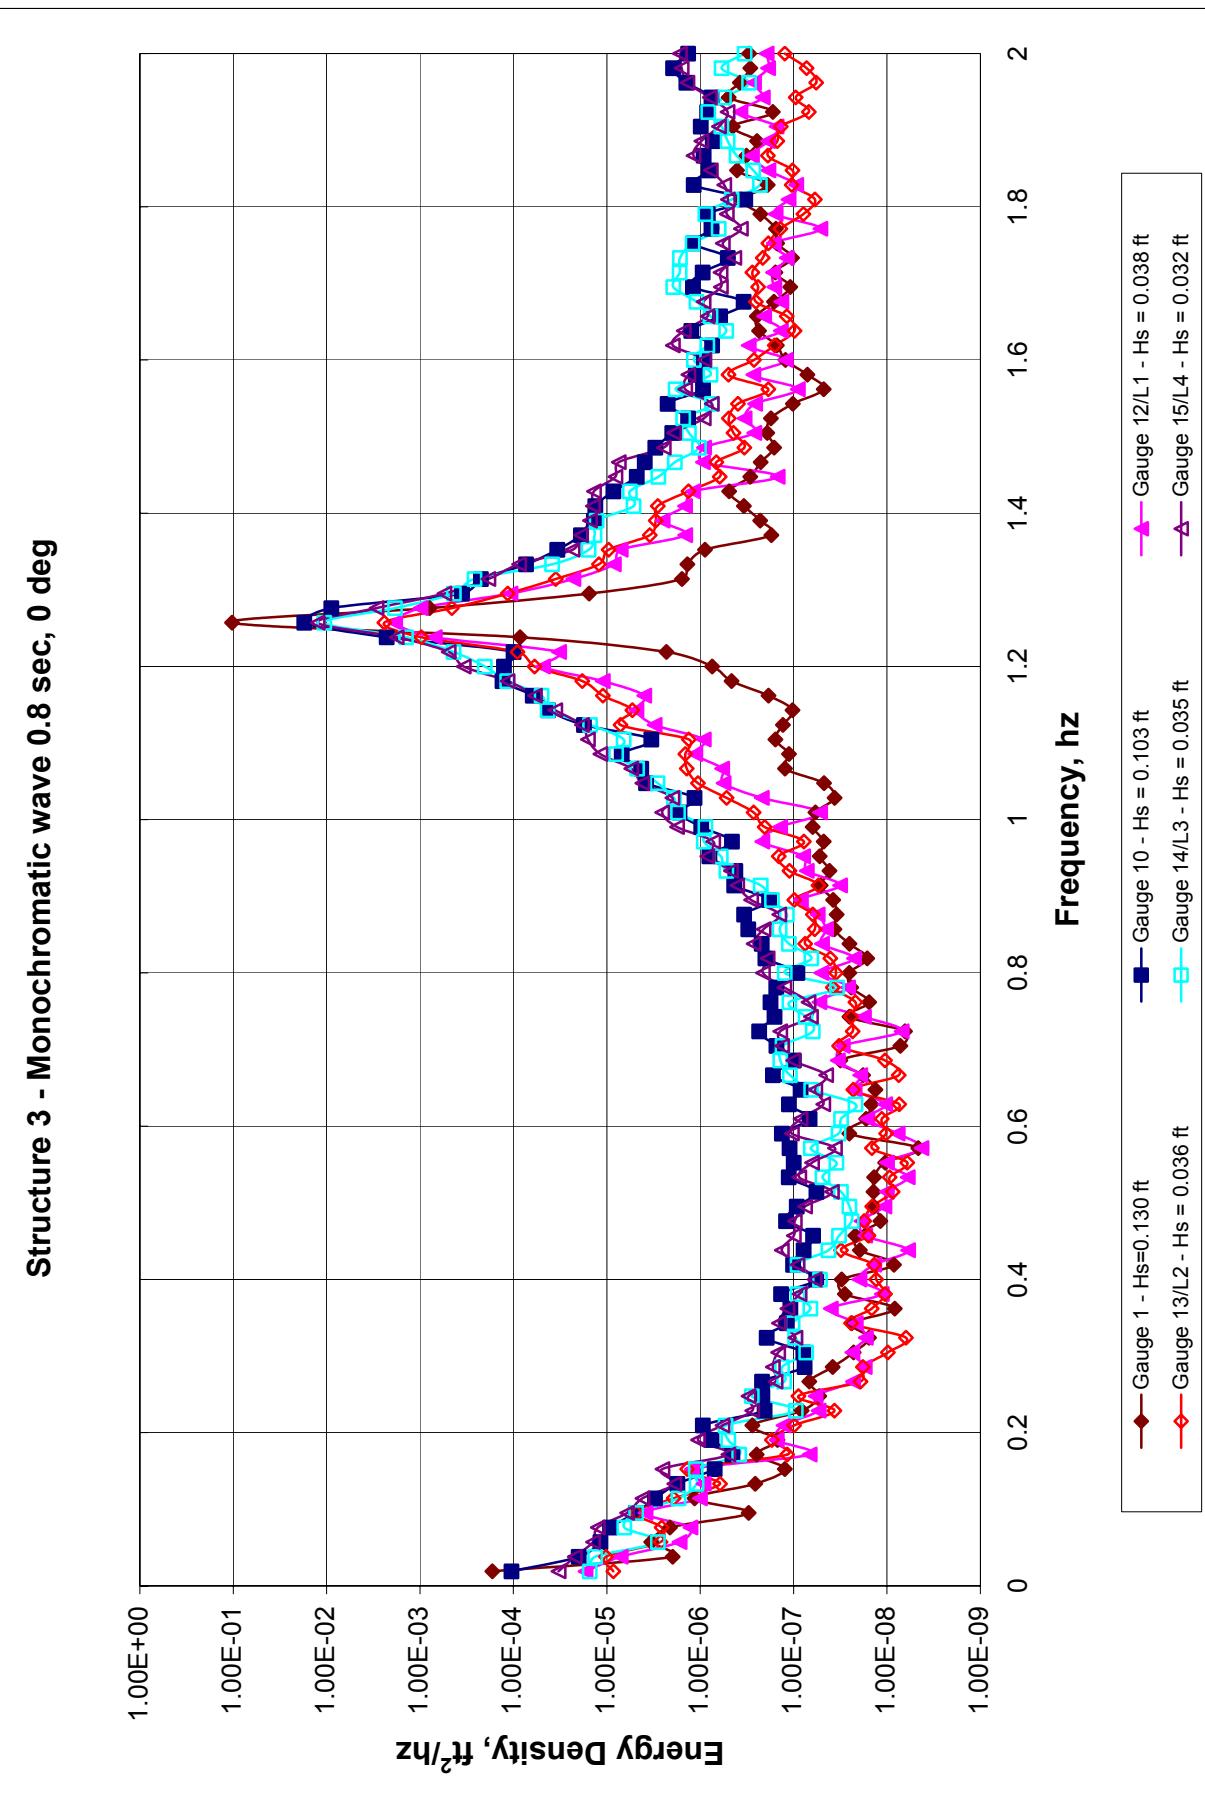

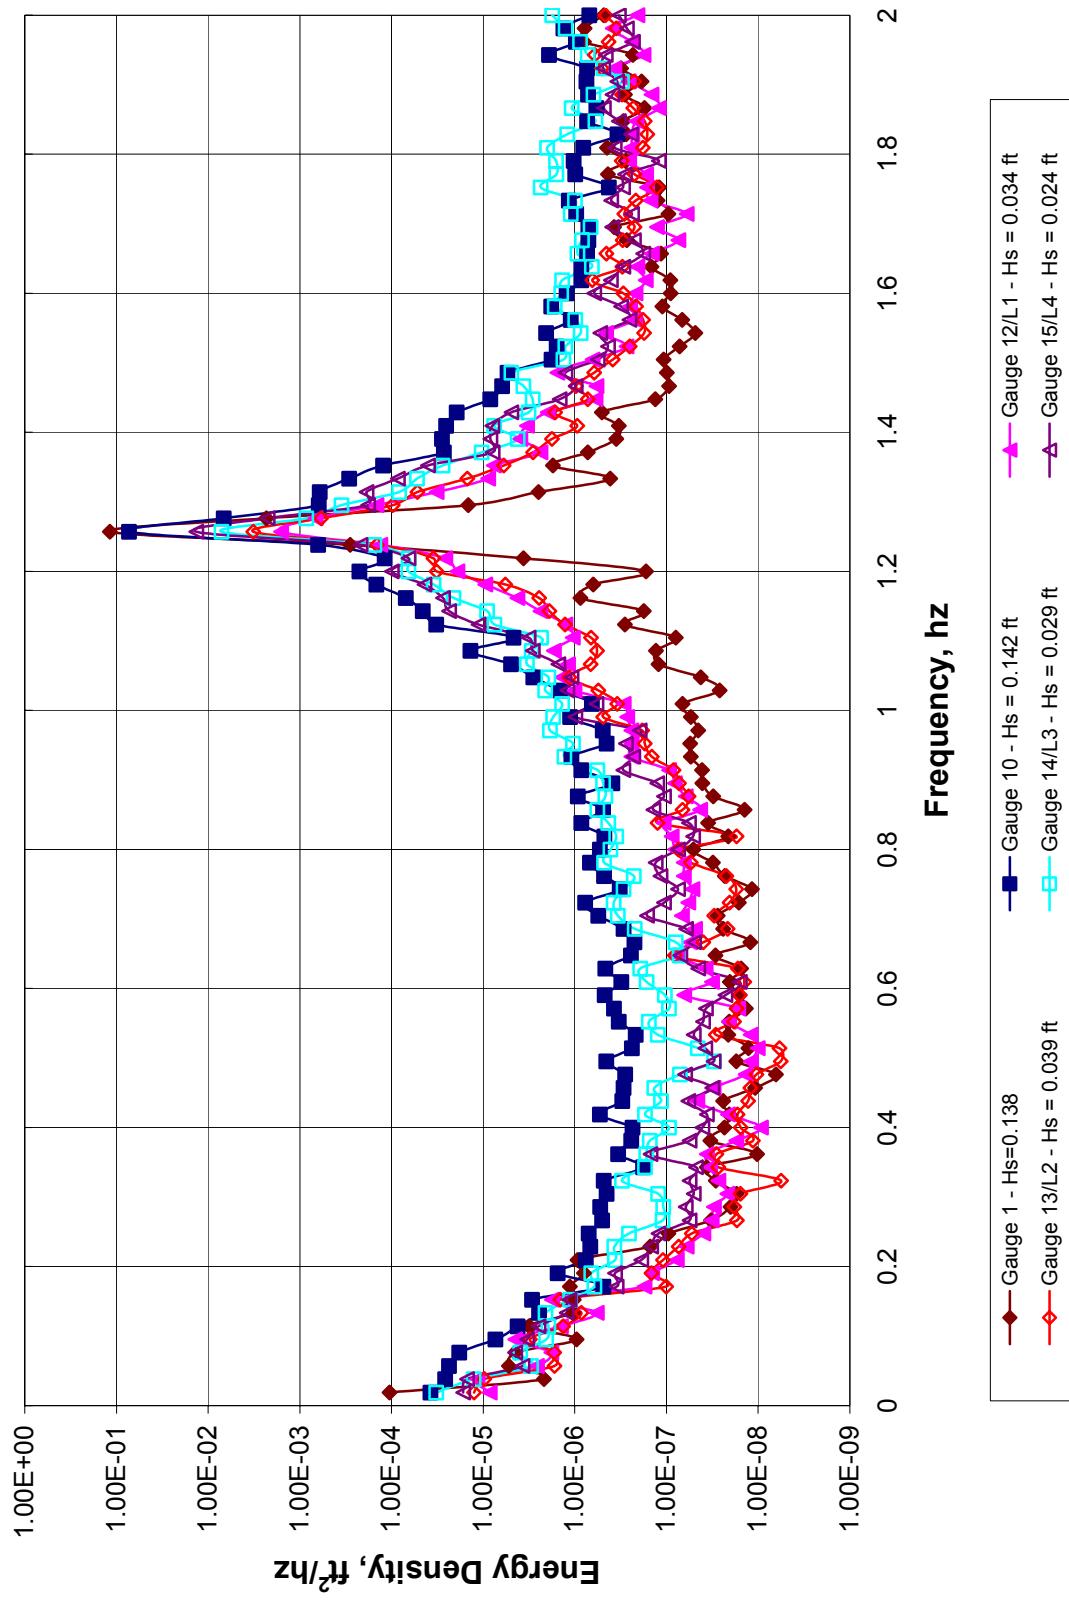

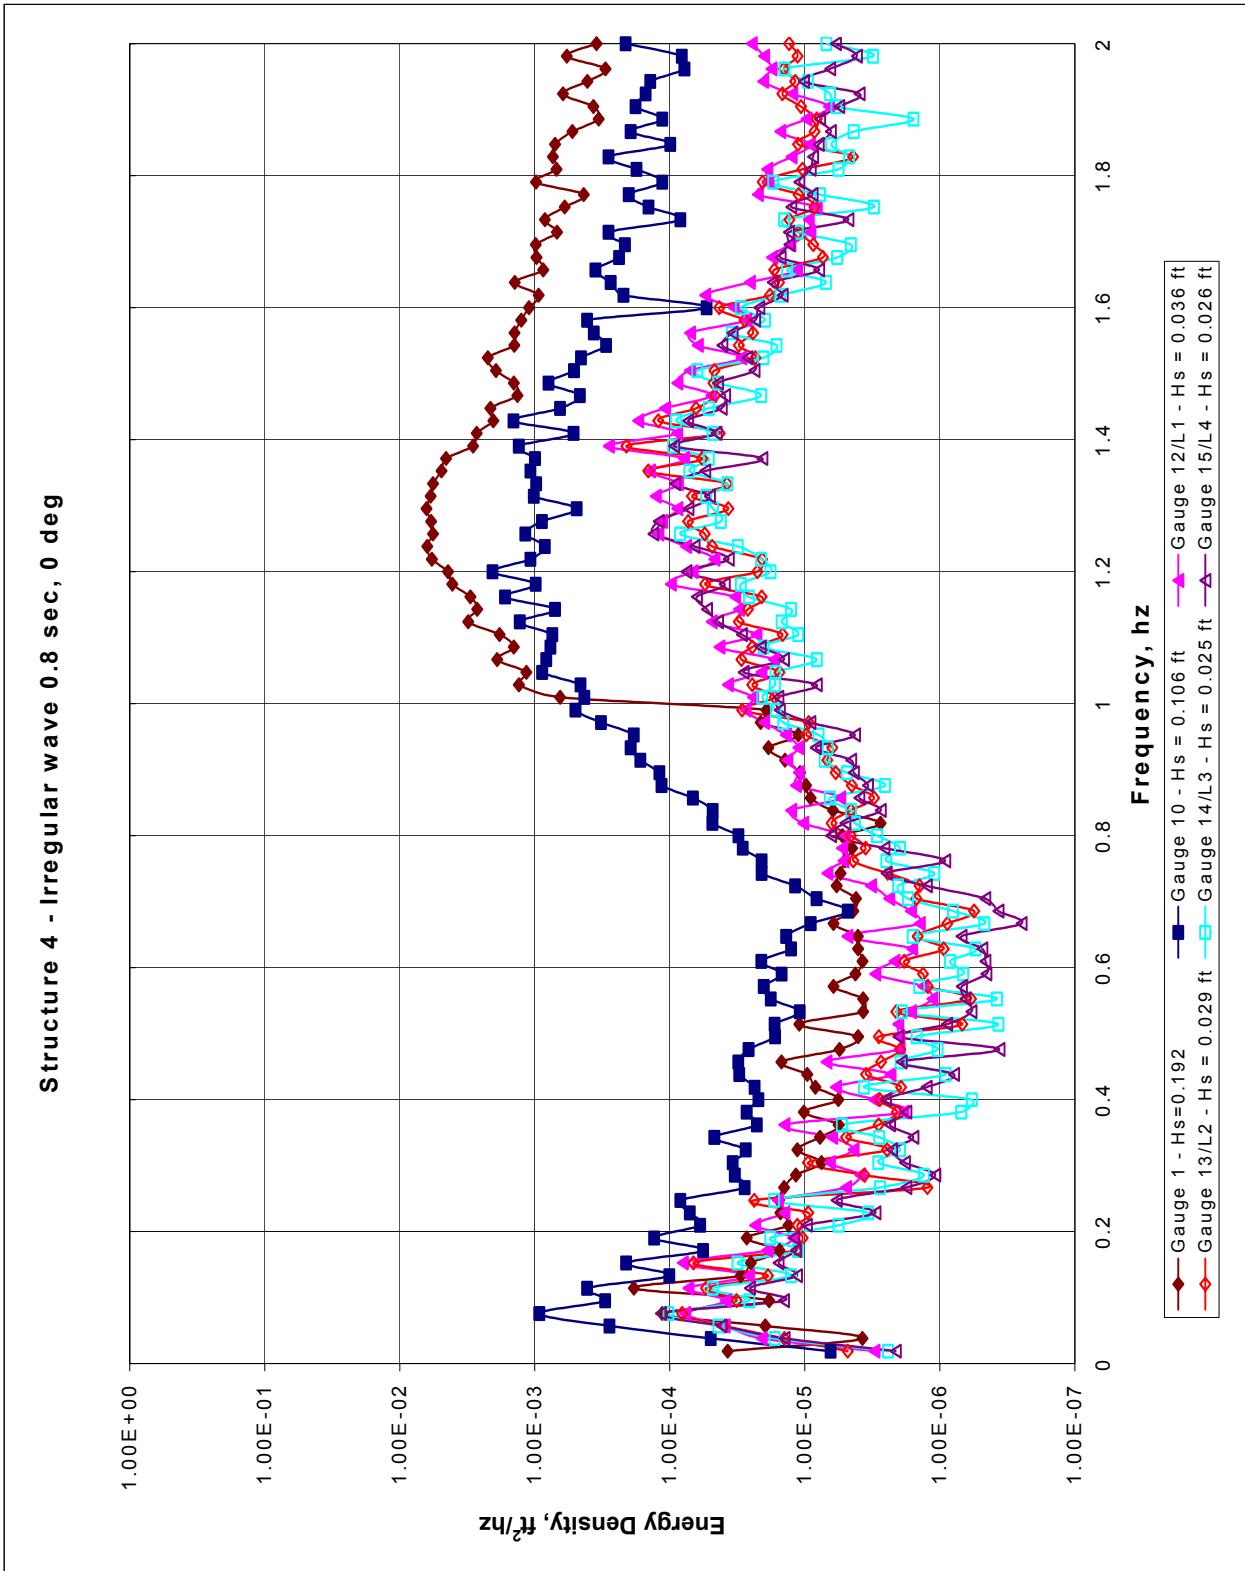

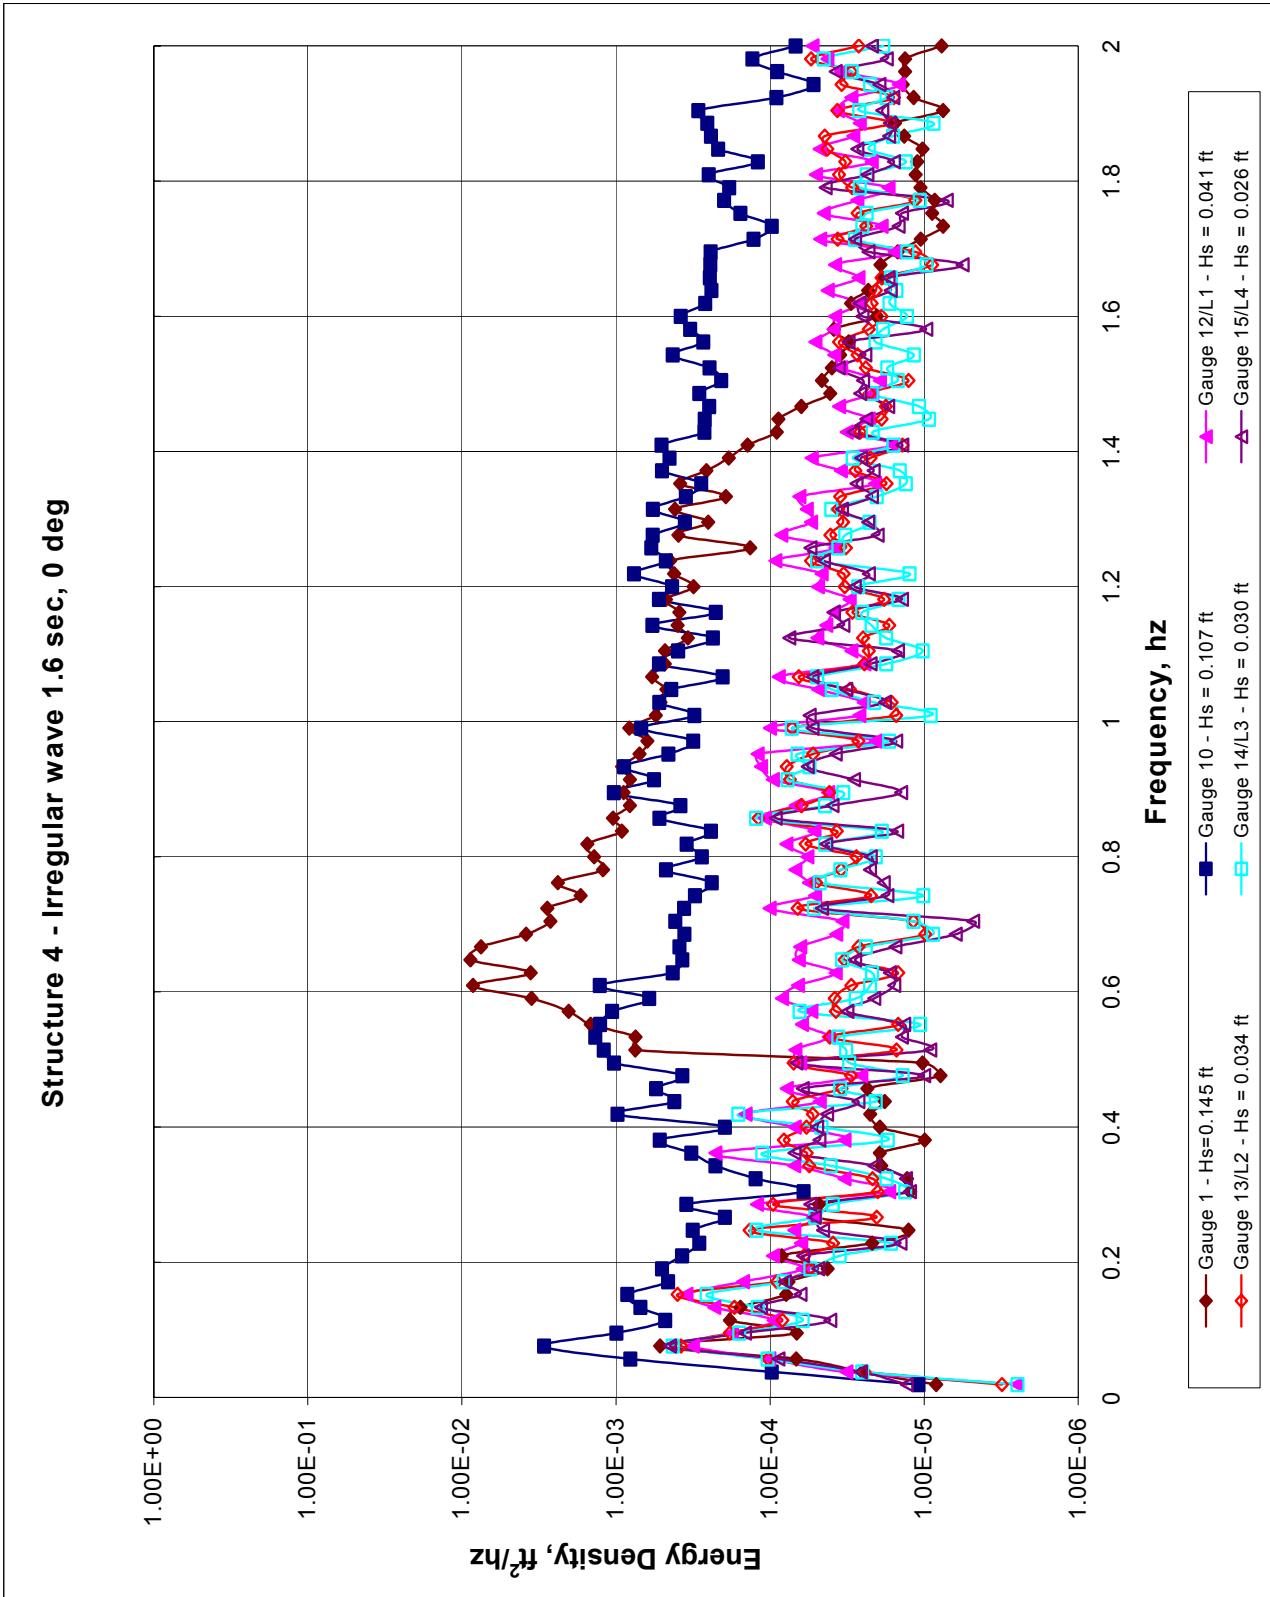

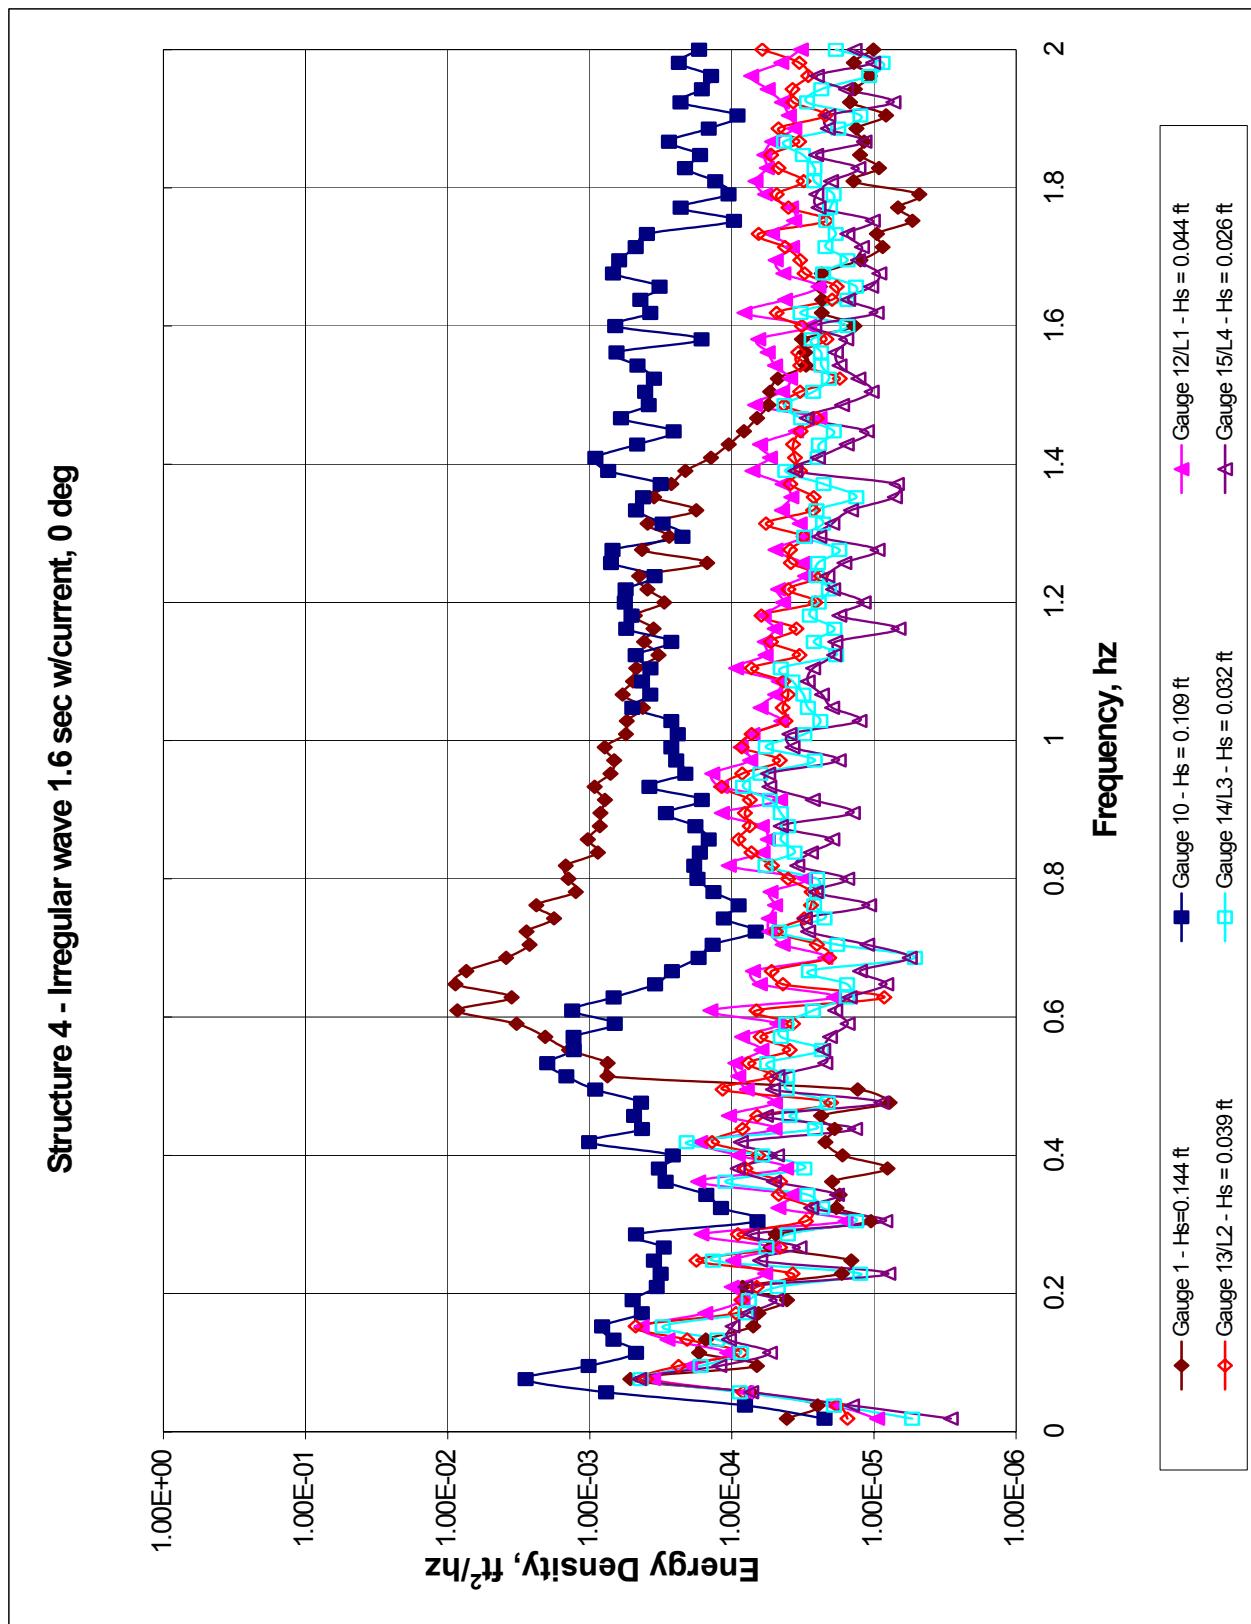

Structure 3 - Monochromatic wave 0.8 sec w/current, 0 deg

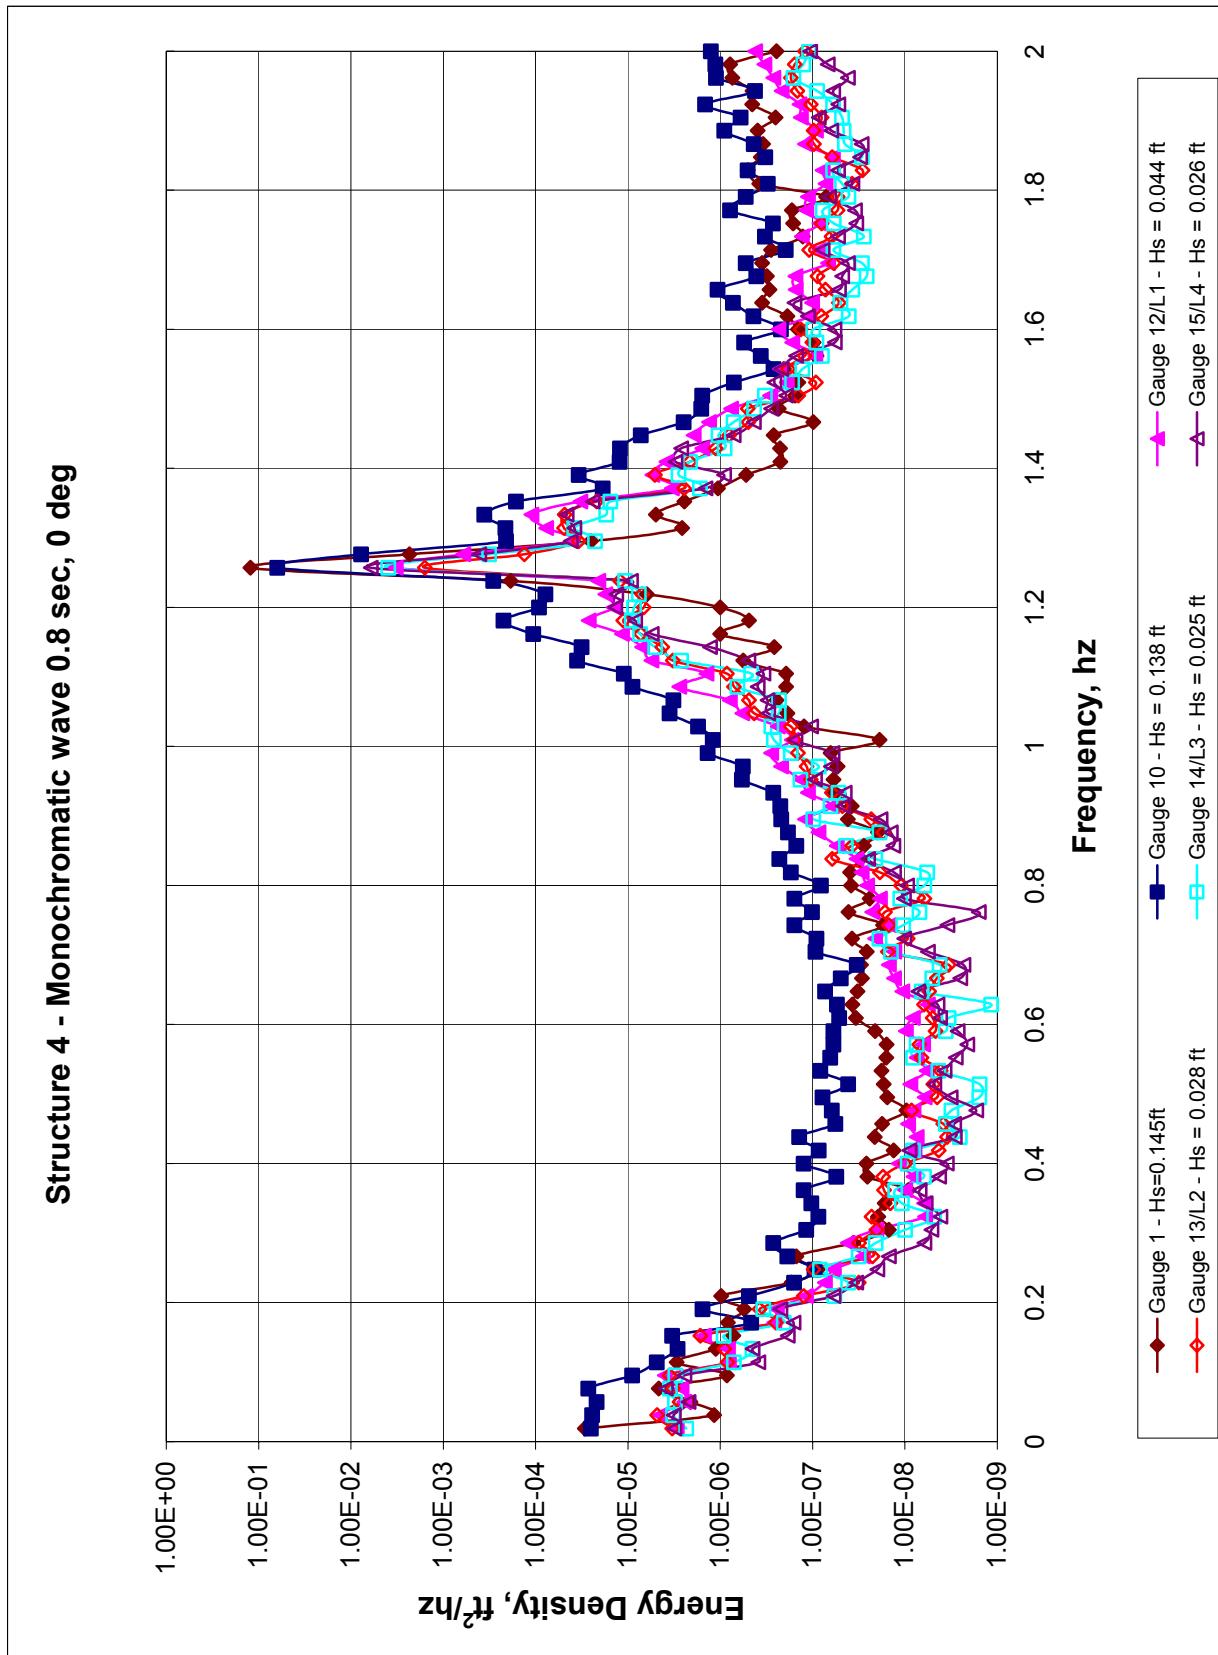

Structure 4 - Monochromatic wave 0.8 sec, 0 deg

Appendix K

Basin Bathymetry

The basin bathymetry is provided in x-, y-, and z-coordinates for each of the four model configurations and structural arrangements. x-, y-, and z-values are presented at the 1:50 scale. The model was operated at the +1.5-m- (+5.0-ft-) mlw water level. Figure K1 shows the origin with the positive x-axis running horizontally to the left and the y-axis running vertically down from the point located in the upper right corner. Due to the large size of each file, this information is presented in ASCII text on the CD accompanying this report.

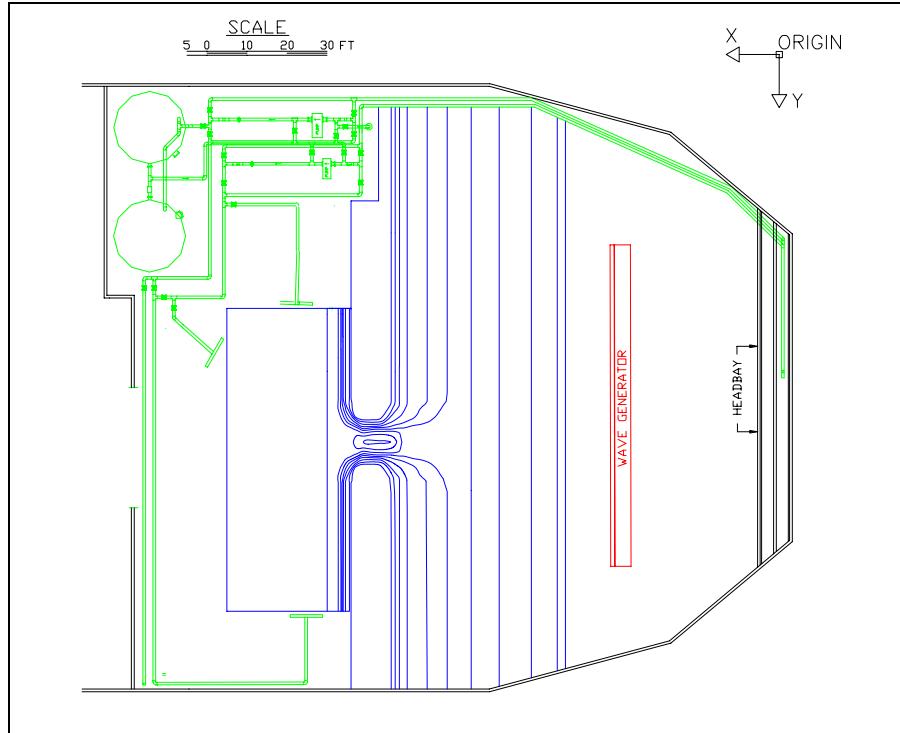

Figure K1. Model layout and origin of axes

Appendix L

Location of Structure 1 Wave Gauges

Tables L1 through L5 list the location and depths, in feet, of the gauges placed in the physical model for Structure 1 wave runs. Table L6 contains the x- and y-coordinates in feet for the shore-parallel breakwater structure used in this model configuration. The rack housing gauges 11-20 is referenced by the letter R, and L denotes the rack that holds wave gauges 21-30. To convert measurements given in feet to meters, multiply by 0.3048.

Location of Structure 2 Wave Gauges

Tables M1 through M5 list the location and depths, in feet, of the gauges placed in the physical model for Structure 2 wave runs. Table M6 contains the x- and y-coordinates in feet for the dogleg jetty structure used in this model configuration. The rack housing gauges 11-20 is referenced by the letter R, and L denotes the rack that holds wave gauges 21-30. To convert measurements given in feet to meters, multiply by 0.3048.

Location of Structure 3

Wave Gauges

Tables N1 through N4 list the location and depths, in feet, of the gauges placed in the physical model for Structure 3 wave runs. The rack housing gauges 11-20 is referenced by the letter L, and R denotes the rack that holds wave gauges 21-30. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix O

Location of Structure 4

Wave Gauges

Tables O1 through O4 list the location and depths, in feet, of the gauges placed in the physical model for Structure 4 wave runs. Table O5 contains the x- and y-coordinates in feet for the parallel jetty structure used in this model configuration. The rack housing gauges 11-20 is referenced by the letter L, and R denotes the rack that holds wave gauges 21-30. To convert measurements given in feet to meters, multiply by 0.3048.

Appendix P

ADV and CIIS Measurement Comparison: Structure 1

This appendix presents plots and tables of normalized spectral energy density versus frequency $S(f)_n$ and vector-mean wave direction versus frequency $\theta_m(f)$ for collocated Coastal Inlets Imaging system (CIIS) and Acoustic Doppler Velocimeter (ADV) measurements for Structure 1, Experiments 4 through 6. $S(f)$ is normalized by the maximum value of the variance spectrum for a given experiment and sensor. Tick (“+”) marks on wave direction curves represent CIIS measurements that meet the coherence cutoff criterion discussed in Chapter 5.

Plot and table titles include 6-digit strings that indicate structure (characters 1-2), experiment (characters 3-4), and gauge arrangement (characters 5-6). For example, S1X4G1 represents Structure 1, Experiment 4, Gauge Arrangement 1. The legend of each plot indicates ADV probe identification number and camera identification number.

Table P1
Nomenclature

Alongshore	Y-axis of model coordinate system
Cross-shore	X-axis of model coordinate system
NaN	Not a number
I	Pixel intensity
f	Frequency (Hz)
$S(f)$	Mean spectral density as a function of frequency presented in units of m^2/Hz for ADV and ℓ^2/Hz for CIIS
$S(f)_n$	Normalized mean spectral density as a function of frequency presented in units of m^2/Hz for ADV and ℓ^2/Hz for CIIS . Normalized by maximum $S(f)$.
$\theta_m(f)$	Vector-mean wave direction as a function of frequency presented in units of deg relative to model coordinate system
$\theta_m(f)_c$	Vector-mean wave direction as a function of frequency presented in units of deg relative to model coordinate system following application of coherence cutoff criteria. Values of not meeting the cutoff criterion are presented as NaN values (i.e., not-a-number).

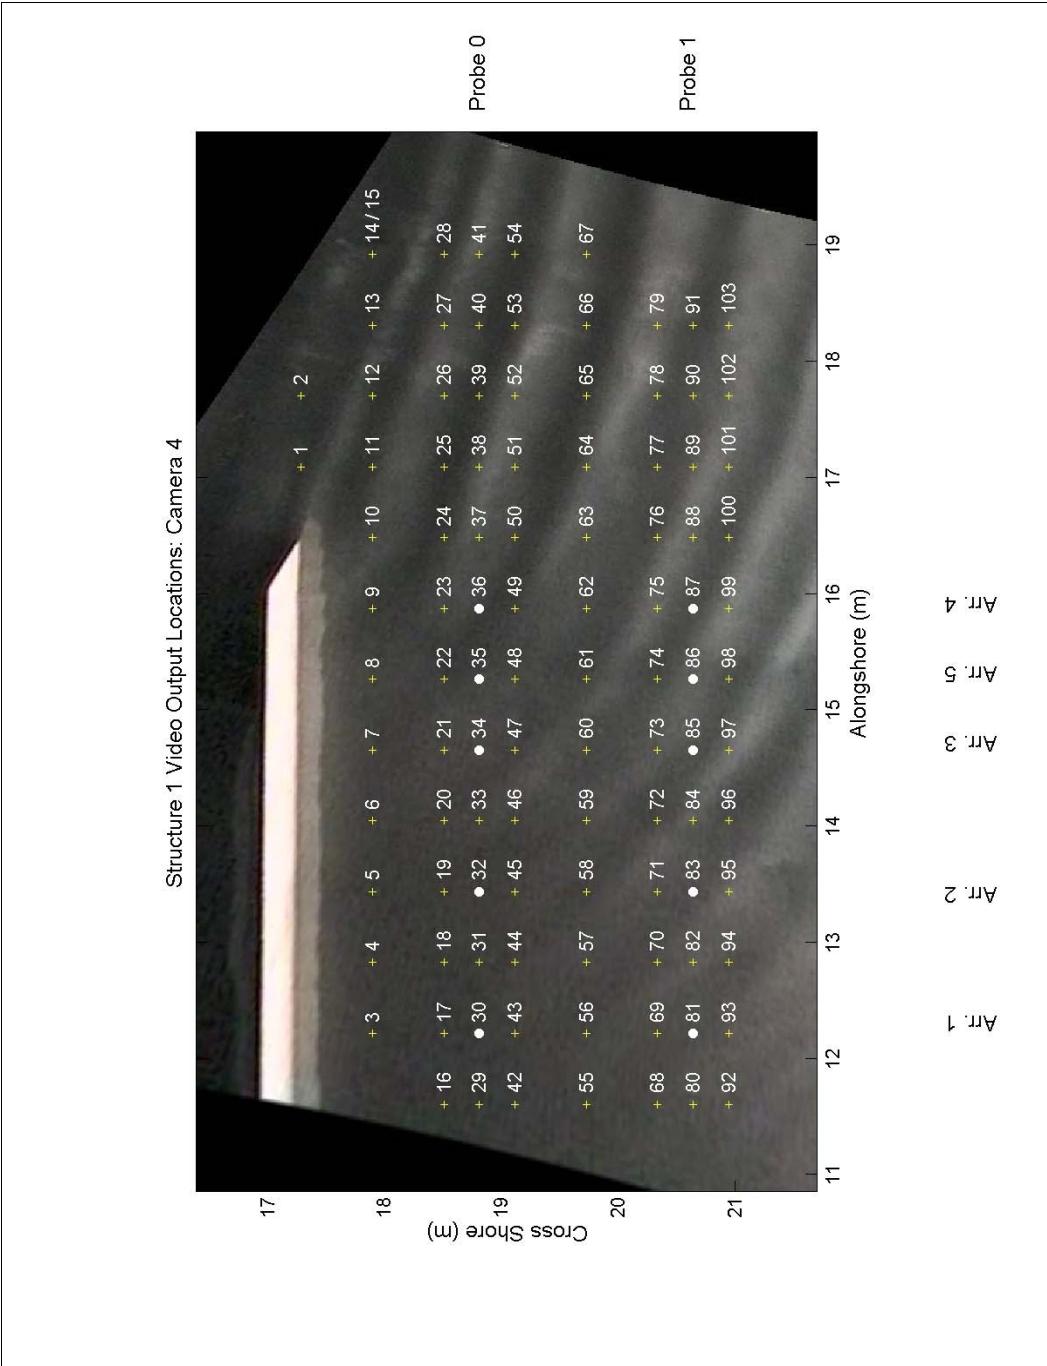

Figure P1. Structure 1, Camera 4 and ADV measurement locations. CIIS output locations indicated by “+”. ADV locations for probe arrangements 1 through 5 indicated by circles

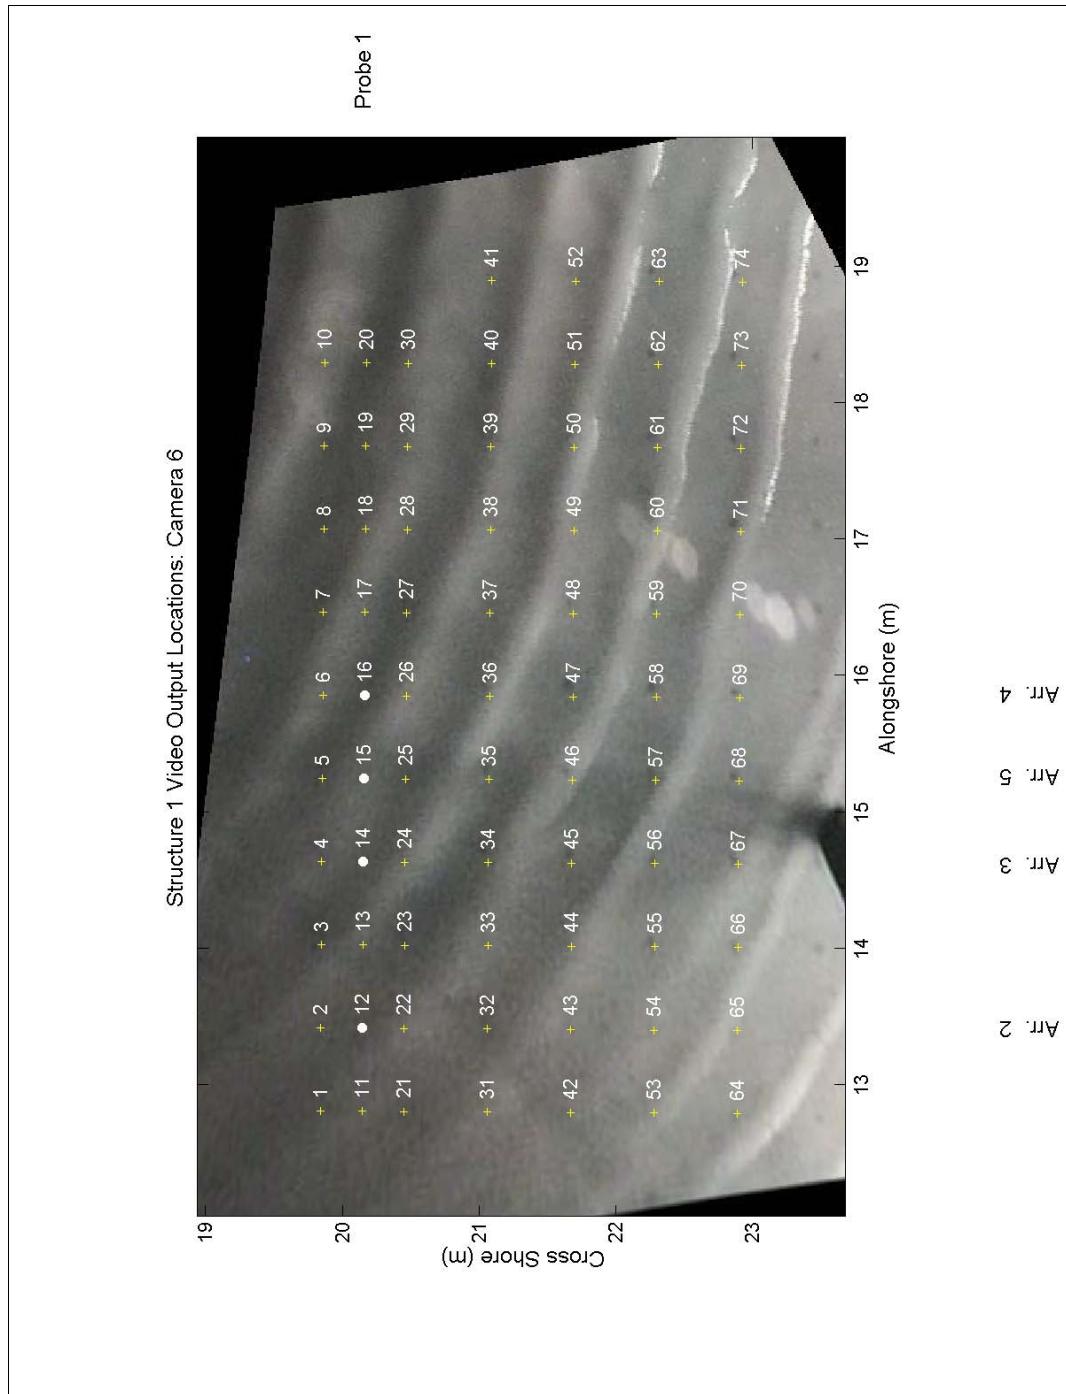

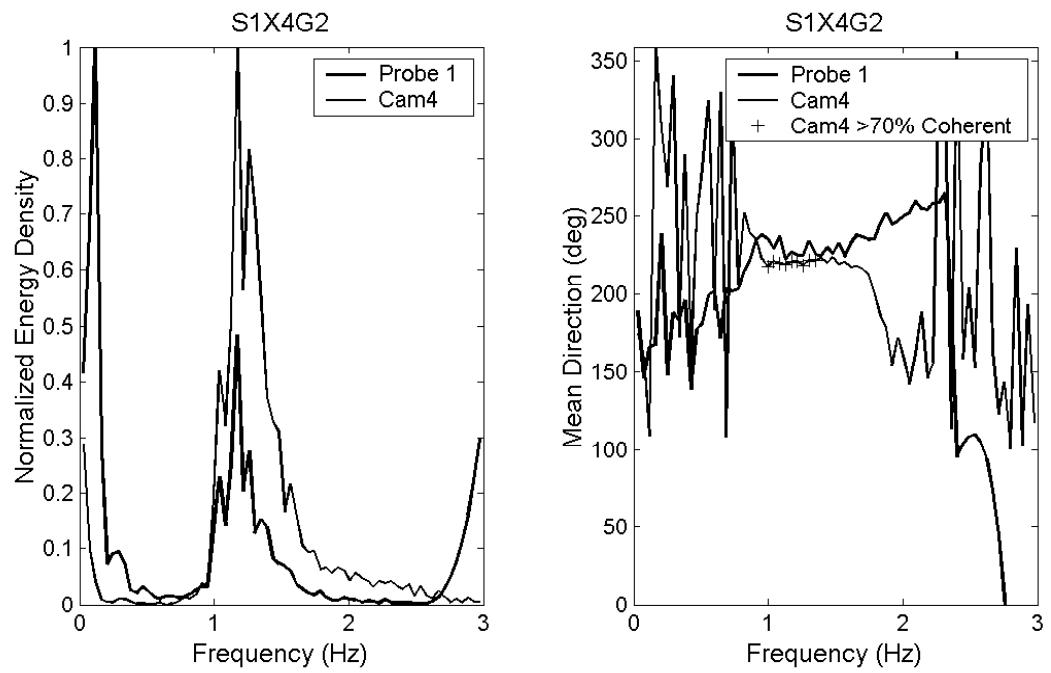

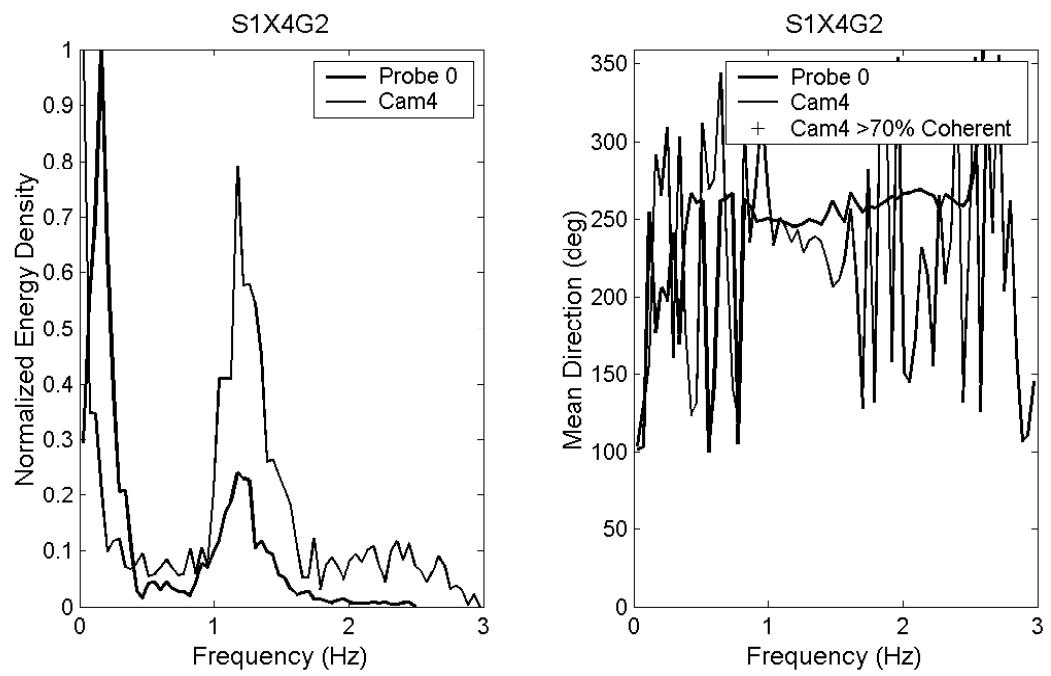

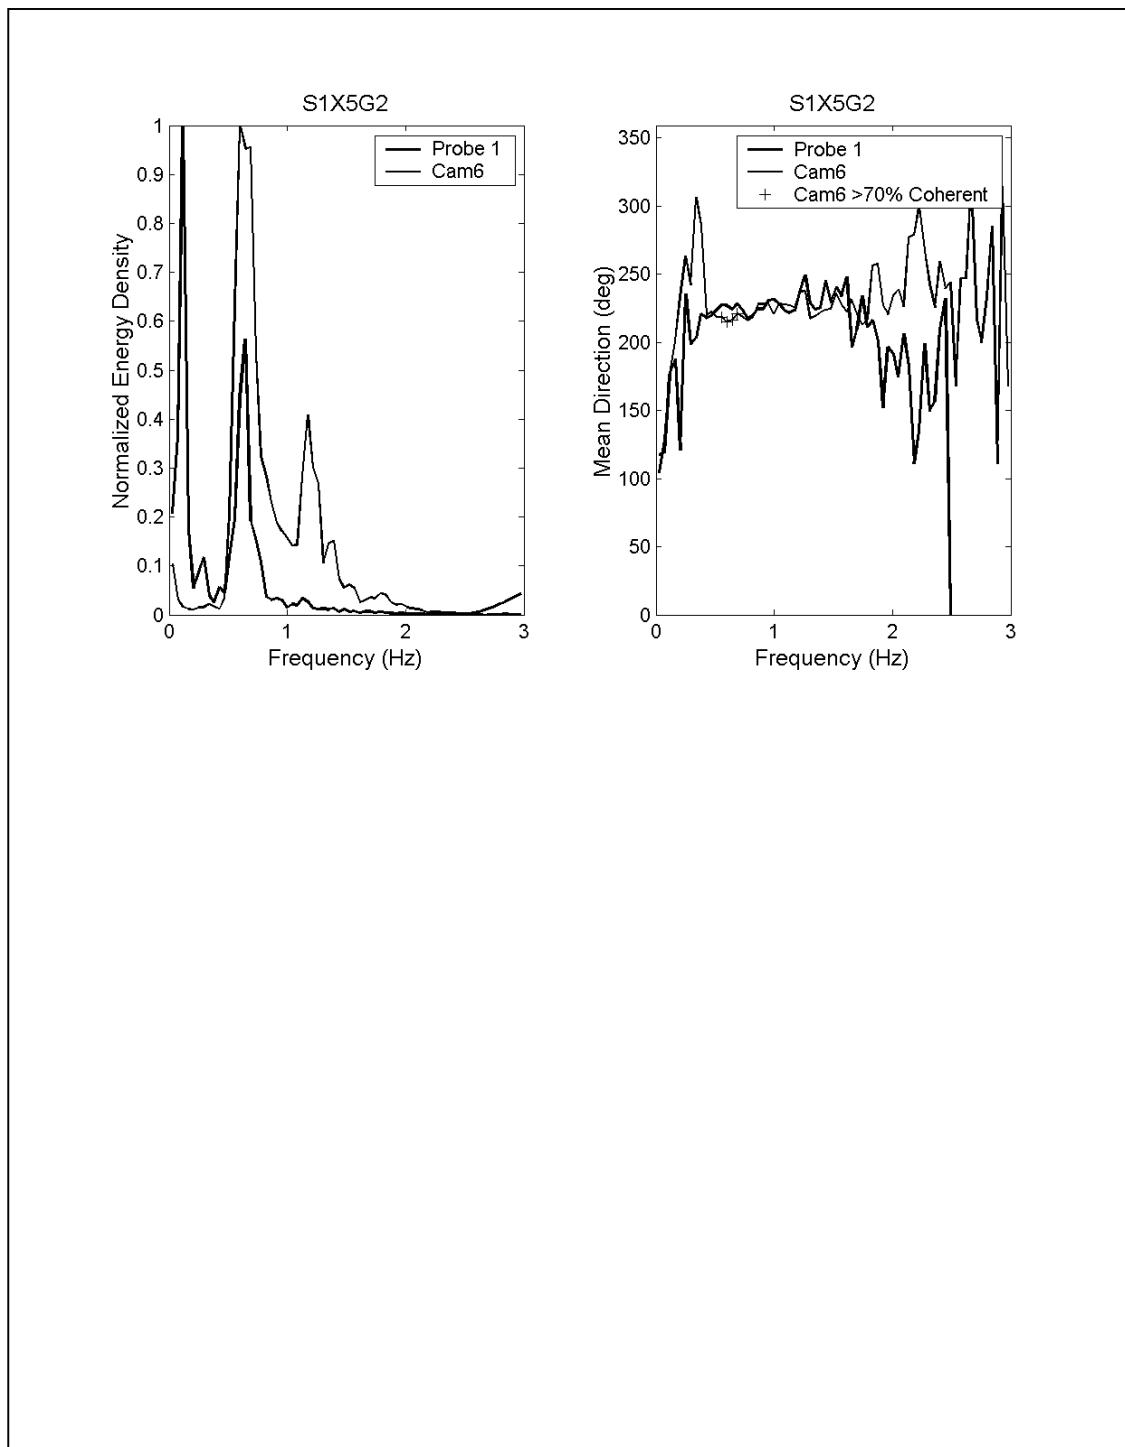

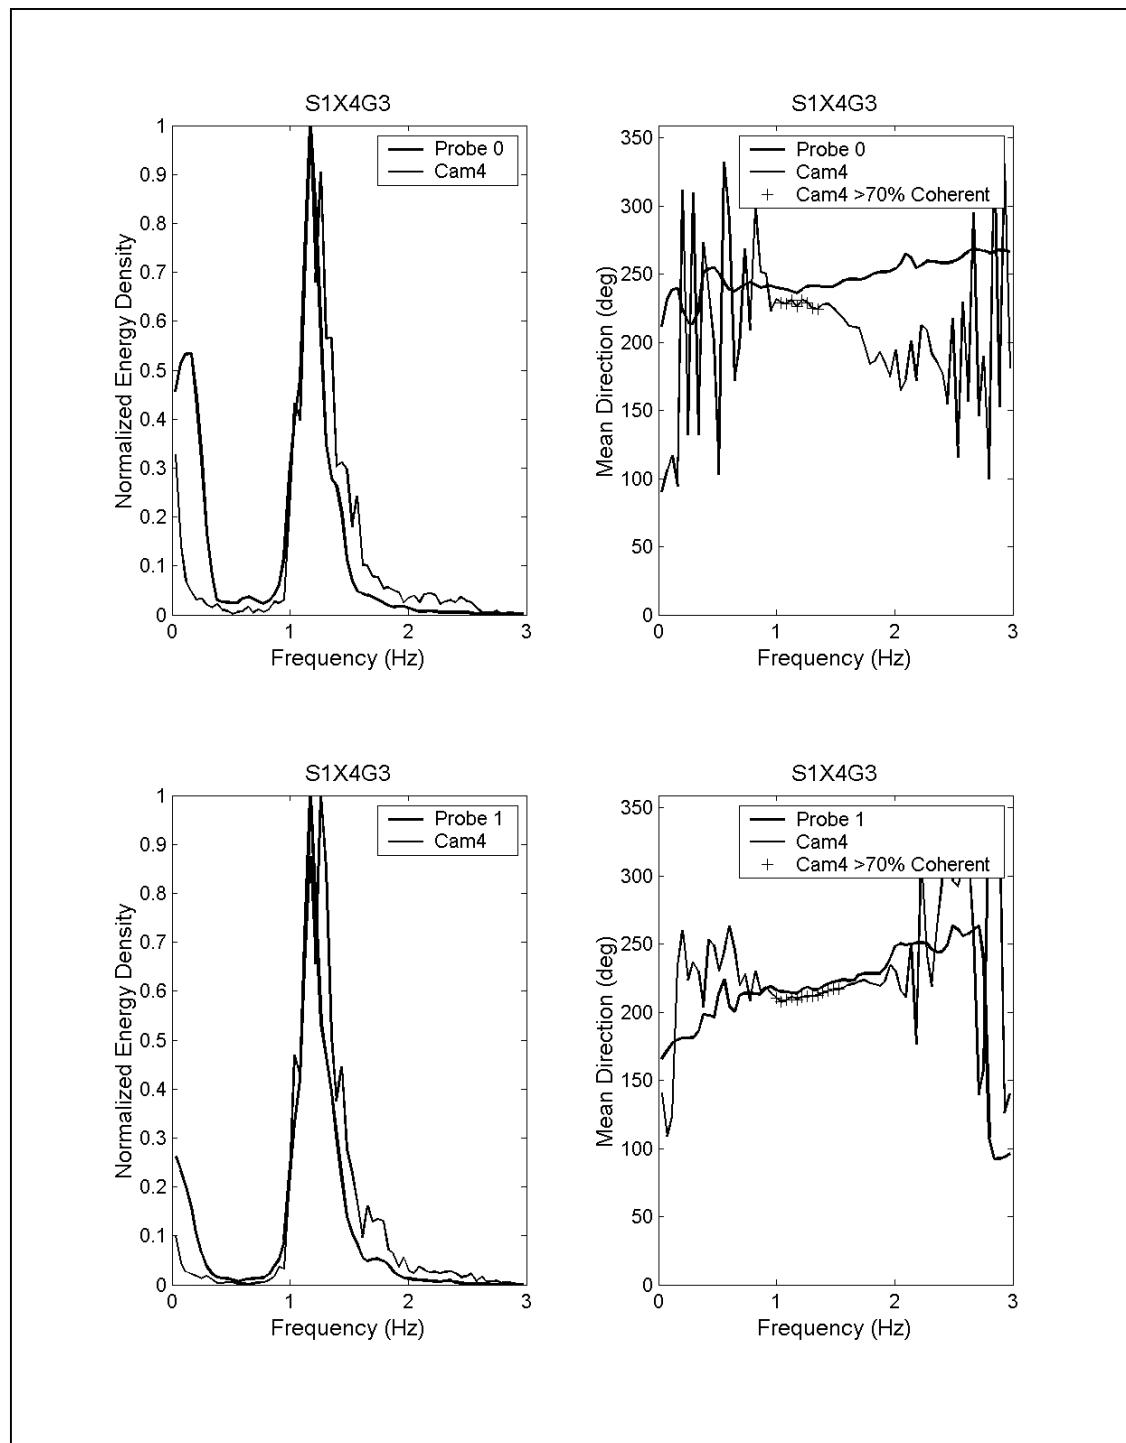

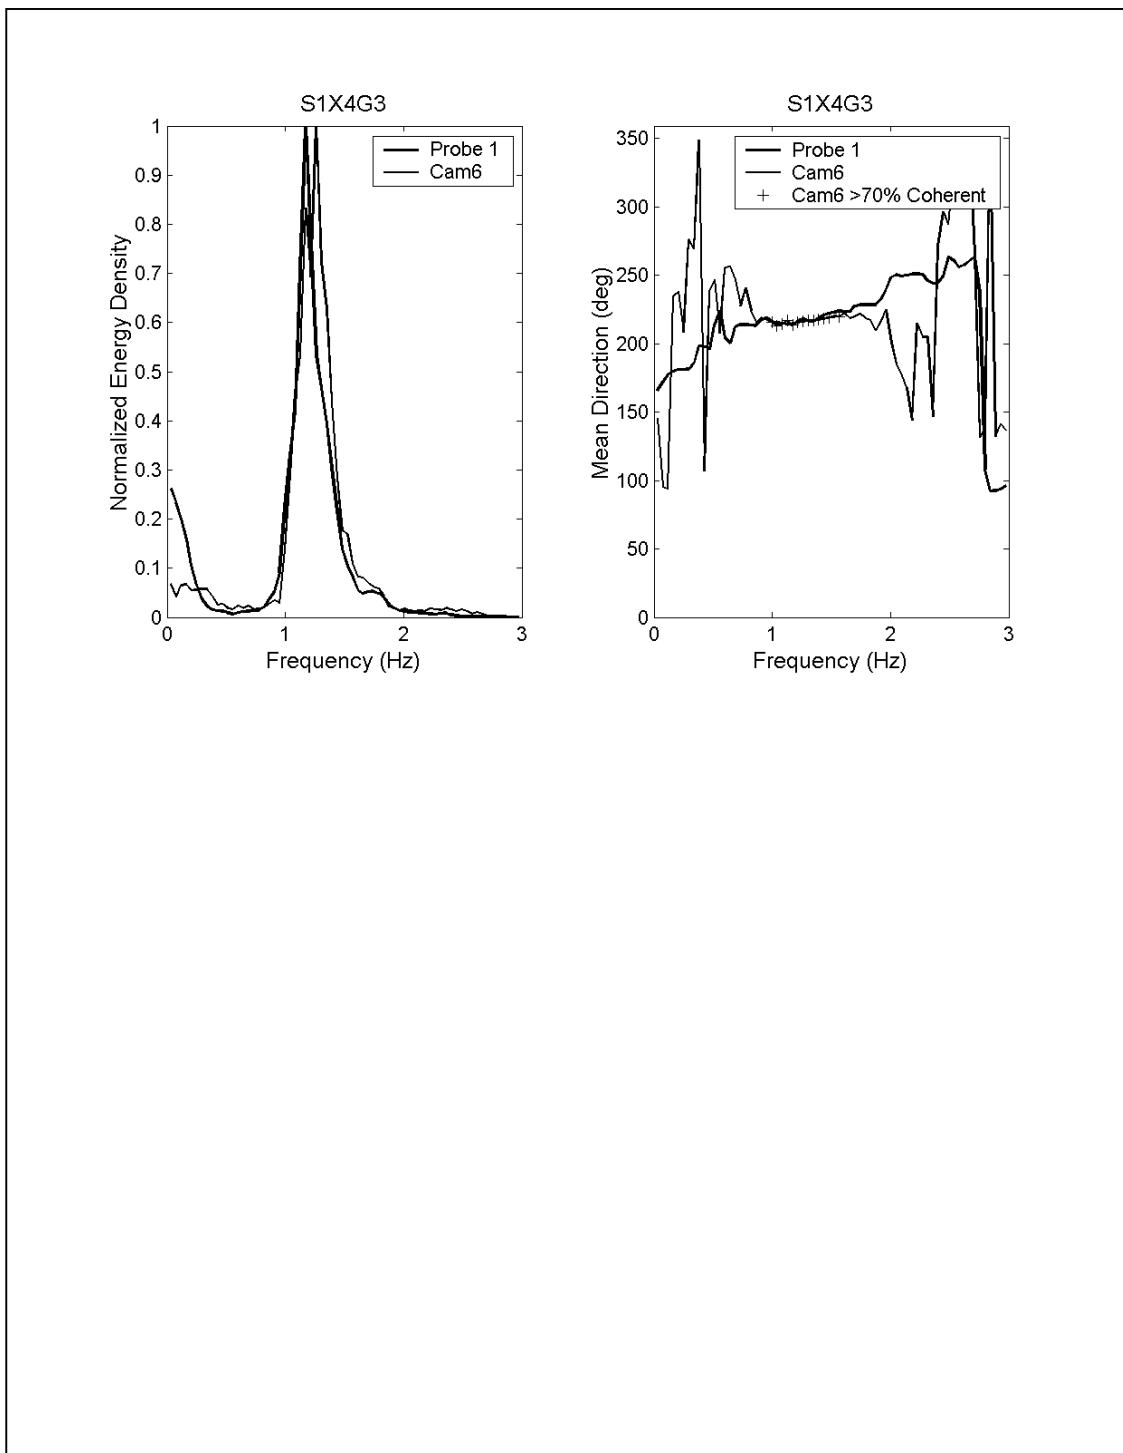

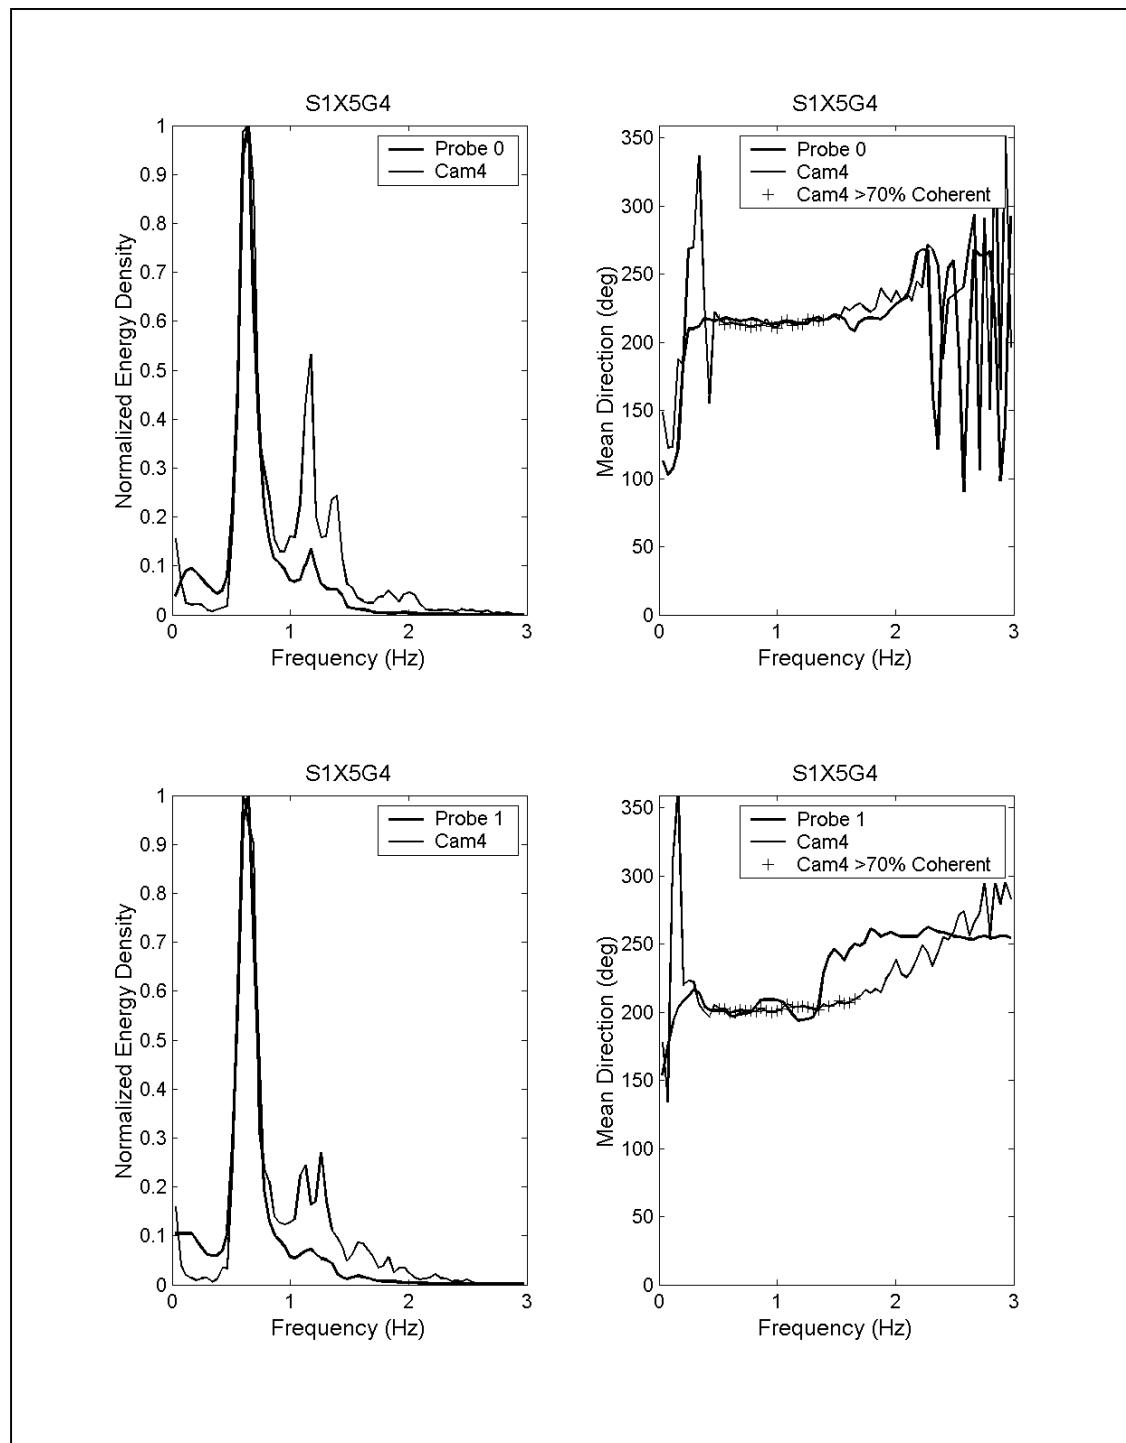

Figure P2. Structure 1, Camera 6 and ADV measurement locations. C1S output locations indicated by “+”. ADV locations for probe arrangements 2 through 5 indicated by circles

Appendix Q

CIIS Measurement Results

Spectral Peak Vector-Mean Wave Direction Plots

Presented in this appendix are rectified snapshot images for each structure and experiment. Superimposed on each image are wave direction vectors that represent the vector-mean wave direction at the peak of the measured spectrum for each Coastal Inlets Imaging System (CIIS) output location in a given camera view. In the physical model coordinate system, alongshore and cross-shore image axis labels correspond to y- and x-axes, respectively.

For each CIIS array location, a wide band about the theoretical spectral peak was searched for a value of maximum energy density and corresponding frequency. Then the corresponding wave direction vector was plotted. For Experiments 1 and 4 the band about the spectral peak ranged between 0.5 and 2 Hz. For Experiments 2 and 5, the band about the spectral peak ranged between 0.3 and 0.7 Hz. For Experiments 3 and 6, the band about the spectral peak ranged between 1.0 and 1.5 Hz.

Vectors without a circled tail represent wave directions that do not meet the coherence cutoff criteria discussed in Chapter 5. Vectors with a circled tail represent wave directions that meet the cutoff criteria. For the sake of graphical visual representation, wave direction vectors are scaled by wave celerity:

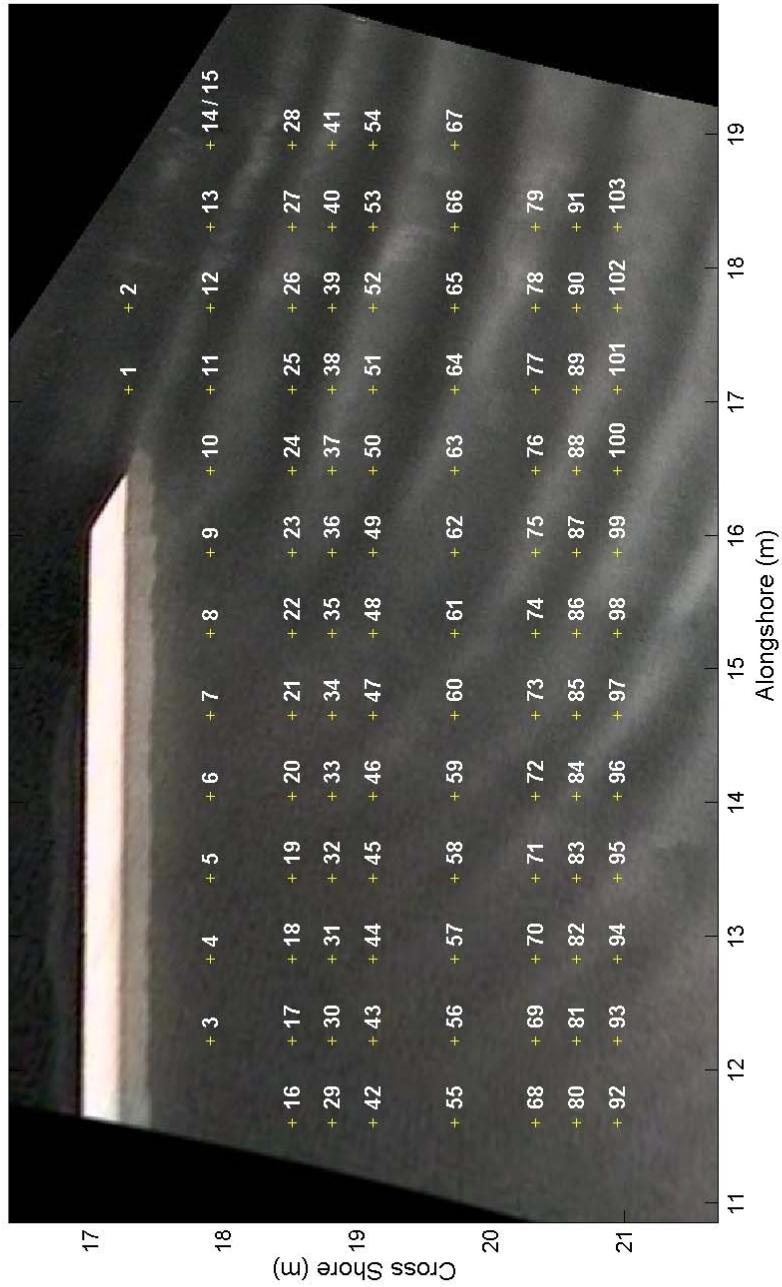

$$k = \sqrt{k_x^2 + k_y^2}$$

$$c = \frac{f}{k}$$

where k = wave number and f = frequency.

Plot titles have either 4- or 5-digit strings that indicate structure (characters 1-2) and experiment (characters 3-4), and c indicates whether a 15-cm/sec current was present in channel (character 5), as well as camera number. For example, “S1X1” represents Structure 1, Experiment 1. “S3X1c” represents Structure 1, Experiment 1, current in channel.

*Form Approved
OMB No. 0704-0188*

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. **PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.**

14. ABSTRACT This physical model study of wave refraction-diffraction at structures typically present at coastal inlets was conducted to provide data sets that would aid in the calibration and verification of numerical wave models. The study was performed in the Coastal Inlet Research Program's (CIRP) idealized inlet experimental basin at the U.S. Army Engineer Research and Development Center (ERDC), Coastal and Hydraulics Laboratory (CHL). Safe navigation, sediment transport into navigation channels, and shoreline erosion are all concerns at coastal inlets and are related to the transformation of waves as they change direction and height due to complex bathymetry and coastal inlet structures. The idealized inlet physical model, created for inlet studies, provided a facility in which to make wave measurements of height and direction in enough detail to document wave diffraction and refraction. Measurements of wave information included use of capacitive wave rods for wave height, acoustic-Doppler velocity sensors for wave direction, and new video-based wave direction measurement system. Four idealized structural configurations were examined with two irregular waves, 0.8 sec, 0.2 ft (6.1 cm), and 1.6 sec, 0.15 ft (4.6 cm), and one regular wave, 0.8 sec, 0.15 ft (4.6 cm). Structure 1 consisted of a shore-parallel breakwater with the wave generator creating shore-normal and 20-deg-angle waves. Structure 2 was a typical dogleg jetty with shore-normal and 20-deg-angle waves. Structure 3 was an unjettied inlet but included flood currents. Structure 4 had parallel jetties at the inlet. Structures 3 and 4 were concerned with wave transportation into the bay. A total of 30 wave gauges were used to acquire data with 20 gauges placed on two movable racks for deployment into specified gauge arrangements. This study also introduced the use of a new technique for acquiring video-based measurements of wave angle, the Coastal Inlets Imaging System (CIIS).
